History of Mithila, Vajji & Anga: From Prehistory to the Contemporary Period vol. 1 General and political history vol 2 socio-cultural-economic history **ISBN Number** : 978-93-344-9415-0

Videha — First Maithili Fortnightly eJournal · ISSN 2229-547X · www.videha.co.in

This volume is designed as a single 8 × 11 inch hardback edition. Maps, charts, diagrams and analytical figures prepared for the volume are reproduced in colour.

Historical names, administrative units and language labels are used according to period and evidence. Their appearance in one chapter does not imply timeless territorial, linguistic or social equivalence.

Editorial Note on Historical Method

The book distinguishes Mahākavi Vidyāpati, the earlier Maithili Padāvalī poet placed before Jyotirīśvara in the adopted framework, from the later Vidyāpati Ṭhakkura associated with the Oiniwar court and Sanskrit/Avahatṭa works. Evidence belonging to one figure is not transferred automatically to the other.

Śrottriya is not projected backward as a fixed medieval Maithil Brahmin sub-caste. In this volume, its emergence as a distinct sub-caste is treated as a much later development, around 1800 CE, on the basis of the Panji/Śākhā-pustak chronology adopted for the project.

Mithila, Videha, Vajji/Vṛji, Anga, Tīrhut, Madhesh/Tarai and modern administrative units are treated as overlapping historical-geographical frames rather than interchangeable names with permanent borders.

Literary memory, mythology, ritual tradition, archaeology, inscriptions, manuscript evidence, administrative records, census categories, ethnography and modern statistics are kept analytically distinct and are used according to the kinds of claims they can support.

Contents

PART I — LAND, ENVIRONMENT AND THE MAKING OF HUMAN LANDSCAPES	23
Chapter 1 — The Physical Foundations of Society.....	24
Chapter 2 — Prehistoric Settlement and Subsistence	32
Chapter 3 — CHALCOLITHIC AND EARLY AGRARIAN COMMUNITIES	42
Chapter 4 — ARCHAEOLOGY OF FOOD AND EVERYDAY LIFE	49
Chapter 5 — ENVIRONMENT, MOBILITY AND SETTLEMENT.....	57
PART II — EARLY HISTORIC SOCIETY: VIDEHA, VAJJI AND ANGA.....	63
Chapter 6 — THE SECOND URBANISATION	64
Chapter 7 — HOUSEHOLD AND FAMILY IN EARLY HISTORIC SOCIETY	72
Chapter 8 — SOCIAL DIFFERENTIATION BEFORE FIXED CASTE NARRATIVES.....	80
Chapter 9 — WOMEN IN EARLY MITHILA-VAJJI-ANGA.....	89
Chapter 10 — AGRICULTURE AND THE RURAL ECONOMY	97
Chapter 11 — CRAFTS AND TECHNOLOGY.....	105
Chapter 12 — Trade, Merchants and Markets.....	113
Chapter 13 — Vaishali as an Economic and Social Centre.....	122
Chapter 14 — Anga and Champa	130
Chapter 15 — Early money and monetisation	138
Chapter 16 — Buddhist and Jain institutional economies	148
Chapter 17 — Education, debate and intellectual communities.....	159
Chapter 18 — Health, medicine and the body.....	168
PART III — RELIGION, RITUAL AND CULTURAL FORMATION	178
Chapter 19 — From Vedic ritual landscapes to regional religious cultures.....	179
Chapter 20 — Buddhism in the social history of Vajji and Videha.....	189
Chapter 21 — Jainism and the Vaishali-Videha landscape	198
Chapter 22 — Śaiva, Śākta and Vaiṣṇava transformations	207
Chapter 23 — Sacred geography.....	216
Chapter 24 — Festivals and calendrical culture.....	225
Chapter 25 — Death, ancestors and life-cycle rites	235
PART IV — EARLY MEDIEVAL AND MEDIEVAL SOCIAL TRANSFORMATION.....	244
Chapter 26 — Land Grants and Changing Agrarian Society	245
Chapter 27 — Village, Market and Town.....	254
Chapter 28 — Labour, Service and Occupational Communities	264
Chapter 29 — Social Classification and Its Historical Formation	272
Chapter 30 — Brahmanical Institutions without Retrospective Caste Projection	281
Chapter 31 — The Panji Tradition	290
Chapter 32 — Women, Marriage and Property in Medieval Mithila	299
Chapter 33 — Karnata and Oiniwar-Period Social Economy	308
Chapter 34 — Islam, Migration and New Social Worlds	317
Chapter 35 — Persianate Culture and Mithila-Anga	326
PART V — LANGUAGE, LITERATURE AND KNOWLEDGE AS SOCIAL HISTORY.....	333
Chapter 36 — Languages Before Modern Standardisation	334

Chapter 37 — Formation of Literary Maithili.....	343
Chapter 38 — The Two Vidyāpatis and Two Historical Contexts	352
Chapter 39 — Tirhuta/Mithilakshar and Scribal Culture.....	360
Chapter 40 — Oral Culture	368
Chapter 41 — Angika and the Eastern Linguistic-Cultural Zone.....	376
Chapter 42 — Bajjika and Western Mithila	385
Chapter 43 — Sanskrit Learning and Scholastic Institutions.....	394
PART VI — MATERIAL CULTURE AND THE ARTS	402
Chapter 44 — Architecture and Settlement	403
Chapter 45 — Dress, Textiles and Ornament.....	412
Chapter 46 — Food History of Mithila, Vajji and Anga	420
Chapter 47 — Mithila Painting Before and Beyond the Modern Art Market	428
Chapter 48 — Mithila Painting and the Twentieth-Century Cultural Economy.....	436
Chapter 49 — Music, Song and Performance	445
Chapter 50 — Theatre and Dramatic Cultures	453
Chapter 51 — Fairs, Markets and Public Culture	461
PART VII — EARLY MODERN AND COLONIAL ECONOMIC TRANSFORMATIONS....	468
Chapter 52 — Mughal-Period Land, Revenue and Agrarian Society.....	469
Chapter 53 — Trade between Bengal, Bihar, Nepal and the Gangetic World.....	477
Chapter 54 — East India Company Expansion and the Remaking of Agrarian Relations.....	485
Chapter 55 — Permanent Settlement and Landed Society	493
Chapter 56 — Indigo and Commercial Agriculture	500
Chapter 57 — Opium and Other Commodity Networks.....	507
Chapter 58 — Famines, Scarcity and Food Security	515
Chapter 59 — Colonial Surveys and the Invention of Social Categories	524
Chapter 60 — Education under Colonialism	532
Chapter 61 — Print Culture	541
Chapter 62 — Railways, Roads and Changing Markets.....	551
Chapter 63 — Labour Migration	559
Chapter 64 — Women and Colonial Modernity	568
PART VIII — NEPAL MITHILA / MADHESH AS A SOCIAL AND ECONOMIC REGION .	576
Chapter 65 — The Historical India–Nepal Borderland Economy.....	577
Chapter 66 — Janakpur as Religious, Commercial and Urban Centre	586
Chapter 67 — Land, Tenancy and Agrarian Society in the Nepal Tarai.....	594
Chapter 68 — Forest Clearance, Malaria Control and Demographic Transformation	602
Chapter 69 — Migration and Settlement.....	610
Chapter 70 — Language, Education and Cultural Institutions in Nepal	617
Chapter 71 — Gender, Citizenship and Household Economy in Madhesh	625
Chapter 72 — Janakpur Art, Crafts and Cultural Economy	633
Chapter 73 — Border Markets, Remittances and Informal Exchange	640
PART IX — POST-1947 / POST-1950 DEVELOPMENT	647
Chapter 74 — Independence, Land Reform and Agrarian Change in Bihar	648
Chapter 75 — Abolition of Zamindari and Its Uneven Consequences	656
Chapter 76 — Agriculture after Independence	664

Chapter 77 — Kosi, Gandak and Major River-Development Projects.....	672
Chapter 78 — Floods as Social and Economic History	680
Chapter 79 — Rural Credit, Indebtedness and Banking	688
Chapter 80 — Cooperatives and Rural Institutions	696
Chapter 81 — Industrialisation and Its Limits	705
Chapter 82 — Bhagalpur Silk and Anga's Textile Economy.....	714
Chapter 83 — Makhana, Fish, Dairy and Specialised Regional Economies	723
Chapter 84 — Education after Independence.....	732
Chapter 85 — Health and Public-Health Transformation	741
Chapter 86 — Roads, Railways, Electricity and Communications	750
PART X — CASTE, CLASS, GENDER AND SOCIAL CHANGE.....	758
Chapter 87 — Historical Formation of Caste Relations	759
Chapter 88 — Dalit Histories	769
Chapter 89 — Adivasi and Forest-Connected Populations Where Regionally Relevant	778
Chapter 90 — Muslims of Mithila and Anga	786
Chapter 91 — Gender and the Household Economy	794
Chapter 92 — Women's Paid and Unpaid Labour.....	803
Chapter 93 — Marriage, Dowry, Inheritance and Changing Family Structures	812
Chapter 94 — Education and Social Mobility.....	821
Chapter 95 — Reservation, Affirmative Action and New Middle Classes	830
Chapter 96 — Rural Elites, Political Economy and Changing Landed Power	839
PART XI — MIGRATION, URBANISATION AND DIASPORA	848
Chapter 97 — The Longue Durée of Migration	849
Chapter 98 — Calcutta/Kolkata and Mithila–Anga Migration	858
Chapter 99 — Delhi, Mumbai and Post-Independence Mobility	867
Chapter 100 — Punjab, Haryana and Seasonal Agricultural Labour.....	876
Chapter 101 — Nepal–India Circular Migration	885
Chapter 102 — Gulf Migration.....	893
Chapter 103 — Remittances and Household Transformation.....	902
Chapter 104 — Urbanisation	910
Chapter 105 — Informal Economies and Street Commerce.....	918
Chapter 106 — Diaspora Cultural Institutions	926
PART XII — CULTURAL MODERNITY AND MASS MEDIA	934
Chapter 107 — Maithili Print and Literary Institutions	935
Chapter 108 — Angika Print and Literary Institutions.....	945
Chapter 109 — Radio and Broadcasting	953
Chapter 110 — Cinema, Video and Recorded Performance	961
Chapter 111 — Newspapers and Public Debate	970
Chapter 112 — Sahitya Akademi, Academies and Institutional Canon Formation	979
Chapter 113 — Women Writers and Alternative Literary Publics	988
Chapter 114 — Videha and Digital Literary Culture.....	997
Chapter 115 — Digital Archives and Cultural Preservation	1007
Chapter 116 — Unicode, Tirhuta and Technological Recognition.....	1015
PART XIII — THE CONTEMPORARY ECONOMY	1022

Chapter 117 — Demographic Structure and Population Change.....	1023
Chapter 118 — Agriculture in the Twenty-First Century.....	1032
Chapter 119 — Land Fragmentation and Rural Livelihoods.....	1042
Chapter 120 — Migration-dependent Economies.....	1052
Chapter 121 — Remittances, Consumption and Housing.....	1062
Chapter 122 — Education Economy and Coaching Migration	1072
Chapter 123 — Health Economy.....	1083
Chapter 124 — Roads, Highways, Airports and Connectivity.....	1092
Chapter 125 — Digital Payments, Mobile Phones and Platform Economies	1103
Chapter 126 — Tourism and Pilgrimage Economies.....	1112
Chapter 127 — Mithila Painting in the Global Market.....	1122
Chapter 128 — GI, Heritage Branding and Intellectual Property	1132
Chapter 129 — Climate Change and Agrarian Risk.....	1142
Chapter 130 — Flood Adaptation and Resilience.....	1151
Chapter 131 — India–Nepal Border Economies after Federalisation	1159
PART XIV — CONTEMPORARY SOCIAL AND CULTURAL CHANGE	1168
Chapter 132 — Family Transformation	1169
Chapter 133 — Changing Marriage Practices	1178
Chapter 134 — Gender, Education and Employment	1187
Chapter 135 — Youth Culture.....	1197
Chapter 136 — Social Media and Language.....	1206
Chapter 137 — Religious Change and Public Ritual	1215
Chapter 138 — Caste in Contemporary Society.....	1224
Chapter 139 — Madhesh, Federalism and Social Citizenship	1234
Chapter 140 — Maithili, Angika and Bajjika in Contemporary Public Life.....	1244
Chapter 141 — Cultural Heritage versus Living Culture.....	1254
Chapter 142 — The Future of the Regional Cultural Economy	1262
PART XV — SYNTHESIS	1271
Chapter 143 — The longue durée of social change.....	1272
Chapter 144 — From Subsistence to Market Integration.....	1281
Chapter 145 — Household, Caste, Class and Gender across Time	1290
Chapter 146 — Riverine Ecology and Economic History.....	1299
Chapter 147 — Language as Social Infrastructure	1307
Chapter 148 — India and Nepal: One Interaction Zone, Multiple Political Economies.....	1315
Chapter 149 — Cultural Persistence, Reinvention and Modern Institutions	1324
Chapter 150 — Conclusion: Socio-Cultural-Economic Histories without Timeless Essences	1332

List of Figures

Figure 1 — A generalized Himalaya–Tarai–Gangetic plain–Anga environmental transect (colour schematic).	25
Figure 2 — Schematic drainage architecture of the study region (colour; not to scale).....	27
Figure 3 — Indicative rainfall contrast among Bihar agro-climatic zones (colour chart).	29
Figure 4 — Evidence control for prehistoric reconstruction: direct context, supported inference, comparison, and rejected retrojection (colour schematic).	33
Figure 5 — Selected prehistoric anchors used in Chapter 2: direct study-zone evidence and explicitly labelled regional comparators (colour schematic; not to scale).	35
Figure 6 — Prehistoric subsistence as a seasonal mosaic rather than a one-way transition from foraging to farming (colour analytical diagram).	37
Figure 7 — Archaeological visibility on an active alluvial plain: burial, exposure and reworking can distort the apparent distribution of prehistoric settlement (colour schematic).	39
Figure 8 — Evidence matrix for selected Chalcolithic and early agrarian anchors. “Strong” indicates direct or repeatedly reported evidence in the cited excavation literature; “reported” indicates more limited evidence. Senuwar is included only as a Middle Ganga comparator.....	43
Figure 9 — Composite technology rather than a copper revolution: stone, bone, copper, ceramics and organic materials remained complementary.....	45
Figure 10 — Seasonal coordination in an early agrarian riverine household. The diagram is analytical rather than a reconstruction of one excavated household.	46
Figure 11 — From early farming to early historic society: continuity, overlap and uneven change rather than a universal technological break.	48
Figure 12 — The preservation filter: archaeological food remains are a selective sample. Absence from the recovered assemblage is not automatically absence from diet.....	49
Figure 13 — From archaeological residue to a defensible history of food. Different evidence classes support different levels of inference.	51
Figure 14 — A riverine foodscape: fields, herds, wetlands, forest edge and river routes fed into household processing and consumption.	52
Figure 15 — Seasonal scheduling and risk buffering in an early agrarian food system. Timings are schematic and varied locally.....	49
Figure 16 — Landscape units and settlement opportunities across the Himalayan foreland–alluvial plain. The transect is schematic and not drawn to scale.....	58
Figure 17 — Four fluvial processes that repeatedly reorganise settlement landscapes: lateral migration, cutoff, aggradation and avulsion.	59
Figure 18 — Archaeological visibility is produced by geomorphology as well as human occupation.	60
Figure 19 — Mobility without a false sedentary/nomadic binary: daily movement, seasonal resource use, exchange, temporary relocation and permanent site shift form a continuum.....	61
Figure 20 — Urbanisation as a convergence rather than an iron-triggered event. The components could develop at different rates and reinforce one another.	65
Figure 21 — Evidence bundle for identifying early urban settlements. No single indicator, including NBPW, is sufficient on its own.	66
Figure 22 — A conceptual Middle Ganga–Anga settlement network. The diagram shows functional interdependence, not a reconstruction of exact ancient roads or geographic coordinates.....	68
Figure 23 — Rural–urban interdependence in the early historic economy. Flows were reciprocal and could include produce, labour, taxes, manufactured goods, markets and institutional services.	70
Figure 24 — Evidence layers for reconstructing household and family. Each source type records a different aspect of domestic and kin life; convergence is stronger than any single indicator.....	73
Figure 25 — Social scales must not be collapsed into one another. Household, kin network, lineage and polity overlap but answer different historical questions.	74
Figure 26 — Household and renunciation as connected social institutions. Material support, mobility, teaching and continuing kin relations linked lay and monastic worlds.	76
Figure 27 — The household as a node in the early historic social economy. Food, care, property, ritual, labour and exchange were interdependent rather than separate spheres.	79
Figure 28 — Social differentiation before fixed caste narratives: several overlapping axes. No single axis explains all early historic hierarchy.....	80
Figure 29 — Normative varṇa scheme and empirical social categories in early Pāli sources. The relationship is not one-to-one.	81

Figure 30 — Differentiated participation in a gana-sangha polity. Collective rule among entitled lineages did not imply universal social equality.	84
Figure 31 — From social differentiation to later caste formations: a long-term process rather than an instant or uniform system.	87
Figure 32 — Evidence windows for reconstructing women's lives in the early historic region. Each source type reveals different aspects and has different limits.	90
Figure 33 — Women's social positions were formed across intersecting domains rather than by gender alone.	91
Figure 34 — Ambapālī and resource control in the Vesālī narrative: from urban status to durable religious patronage.	92
Figure 35 — Female religious and social pathways: opportunity and constraint coexisted.	93
Figure 36 — Early historic agriculture as a coupled system: land, water, seed, labour, livestock and storage had to work together.	98
Figure 37 — Schematic annual agrarian calendar for the Middle Ganga plains. It shows seasonal coordination, not a fixed calendar for every locality.	99
Figure 38 — Rural production and the competing claims on surplus: reproduction, reserves, labour, exchange, taxation and gifts drew on the same harvest.	101
Figure 39 — Evidence control for the rural economy of Mithila–Vajji–Anga: local archaeology has the strongest place-specific claim; more distant evidence requires stronger qualification.	102
Figure 40 — The craft production chain: raw material, preparation, transformation, finishing, circulation and repair/discard form a sequence of technological decisions.	105
Figure 41 — Evidence for local production becomes stronger when finished objects are joined by tools, raw material, unfinished pieces, waste and production features.	106
Figure 42 — Craft production as a distributed regional network linking resources, households, specialist workshops, markets, urban consumers, institutions and repair/recycling.	110
Figure 43 — Preservation bias: pottery and stone are much more visible archaeologically than wood, textiles and fibres. The bars are schematic, not measured values.	111
Figure 44 — Trade reconstruction is strongest when archaeology, texts, landscape and institutions converge.	113
Figure 45 — Markets and exchange operated at several nested scales, from households to long-distance networks.	116
Figure 46 — Commercial roles formed a network of producers, traders, financiers, carriers, markets and institutions rather than one homogeneous merchant class.	118
Figure 47 — Conceptual Ganga–Vajji–Anga exchange corridor; schematic, not a measured traffic map.	120
Figure 48 — Vaiśālī must be reconstructed by converging evidence, not by a single source.	122
Figure 49 — Vaiśālī as an urban system linking civic core, neighbourhoods, institutions, hinterland and routes.	124
Figure 50 — The city's social economy depended on interacting groups, not a single civic elite.	126
Figure 51 — Vaiśālī is an archaeological palimpsest: visible monuments and early urban history are not the same layer.	128
Figure 52 — Anga–Campā must be reconstructed from distinct evidence streams before they are combined.	130
Figure 53 — Campā as a riverine urban system: conceptual relationships among city, Ganga corridor, hinterland and markets.	131
Figure 54 — Selected excavated horizons at Campā: sequence and rebuilding rather than a single founding moment.	132
Figure 55 — Campā's economy depended on reciprocal flows among rural producers, urban households, merchants, crafts and institutions.	134
Figure 56 — Early money and monetisation: distinct evidence streams must be combined before historical inference.	138
Figure 57 — A punch-marked silver coin as a material process from metal supply to deposition.	139
Figure 58 — Selected monetary evidence in the middle and eastern Ganga corridor; conceptual, not a measured map.	142
Figure 59 — Monetisation as a spectrum of overlapping practices rather than an on/off condition.	142
Figure 60 — Religious institutional economy redistributed resources through reciprocal but non-equivalent flows among donors, renunciants, material provision and social value.	149
Figure 61 — Buddhist support combined individual restrictions on money and property with recurring provision for monastic life and collective continuity.	150
Figure 62 — The Jain fourfold Saṅgha linked monks and nuns practising strict renunciation with laymen and laywomen who remained within household economic life.	154
Figure 63 — Regional evidence from Vaiśālī and Campā must be distinguished from comparative early Indian evidence and from later endowed monastic systems.	157
Figure 64 — Early intellectual history requires separate control of textual, institutional and material evidence before synthesis.	159
Figure 65 — The Videha debate traditions model intellectual life as an interaction among patronage, established teachers, questioning and reputation.	162
Figure 66 — Campā's textual landscape brings Brahman students, an itinerant Buddhist Saṅgha, household audiences and other wandering teachers into one urban field.	164
Figure 67 — Knowledge circulated among Videha/Mithilā, Vaiśālī/Vajji, Campā/Aṅga and the Magadhan corridor through mobile people and institutions rather than a centralized university system.	166

Figure 68 — Early health history requires separate control of archaeological, Buddhist, Jain and medical/royal evidence before synthesis.	169
Figure 69 — Buddhist monastic care could turn illness into collective duties of nursing, provisioning and temporary rule adaptation.	171
Figure 70 — Urban water and drainage infrastructure can alter bodily exposure without by itself proving disease rates or a formal public-health administration.	173
Figure 71 — Early Buddhist, Jain and specialist-medical traditions negotiated bodily suffering through different combinations of restraint, care and treatment.	176
Figure 72 — Regional religious history requires separate control of Vedic texts, archaeology, śramaṇa traditions and later monumental evidence.	180
Figure 73 — The Śatapatha Brāhmaṇa remembers Sadānirā as a ritual-cultural threshold; the narrative should not be read as a literal fire-clearing or single-migration map.	180
Figure 74 — Courtly ritual, wandering renouncers, urban/household patrons and communal institutions formed an overlapping regional religious ecology.	184
Figure 75 — Late Vedic, śramaṇa and Mauryan/post-Mauryan layers overlap; sequence does not imply disappearance of earlier practices.	187
Figure 76 — Buddhist social history requires separate control of discourse, Vinaya, archaeology and later memorial traditions before synthesis.	190
Figure 77 — Mithilā/Videha and Vesālī/Vajji function as distinct but connected regional nodes for teachers, patrons, householders, elites and monastics.	191
Figure 78 — The Ambapālī narrative links control of resources, meal patronage, status competition, land donation and the creation of durable monastic space.	193
Figure 79 — Buddhist regional embedding developed through overlapping phases of itinerancy, seasonal residence, regulated community life and civic-monumental memory.	196
Figure 80 — Jain social history requires Jain texts, Buddhist external evidence, archaeology and later sacred memory to be controlled separately before synthesis.	198
Figure 81 — The Kalpa Sūtra tradition remembers repeated rainy-season residence at Vaiśālī–Vāṇijagrāma, Mithilā and Campā–Pṛṣṭhacampā; the figures express regional recurrence, not a contemporary travel diary.	200
Figure 82 — The fourfold Jain community links monks, nuns, laymen and laywomen through differentiated forms of renunciation, material support and ethical participation.	203
Figure 83 — The Vaiśālī–Videha Jain landscape is best modelled as overlapping mobility, seasonal residence, lay–monastic networks and remembered regional nodes rather than a single sectarian territory.	205
Figure 84 — Evidence for Śaiva, Śākta and Vaiṣṇava transformation must be separated into inscriptional, material, textual and archaeological streams before regional synthesis.	208
Figure 85 — Early-medieval religious transformation is modelled as institutional thickening and overlap, not a single conversion line from earlier ritual to three mutually exclusive sects.	209
Figure 86 — Selected regional anchors show different evidentiary strengths: Mithila’s sculptural plurality, Vaiśālī’s layered sacred landscape, Aṅga–Mandar’s inscriptional Vaiṣṇava anchor, and the wider eastern Bihar corridor.	212
Figure 87 — Sectarian traditions became socially durable through linked processes of patronage, materialisation, ritual specialists, public practice, and the continued repair or reuse of sacred objects and places.	214
Figure 88 — Sacred geography must be reconstructed from separately dated textual, archaeological-epigraphic, ritual and later pilgrimage evidence before synthesis.	217
Figure 89 — A sacred centre can emerge through repeated association, materialisation, route formation and renewal; the sequence is cumulative rather than mechanically linear.	219
Figure 90 — Selected regional anchors illustrate different kinds of sacred evidence in Mithila–Videha, Vajji–Vaiśālī and Aṅga; their dates and evidentiary strengths are not uniform.	221
Figure 91 — Sacred centres could concentrate recurring demand for hospitality, household support, specialist labour and transport while remaining embedded in wider local economies.	223
Figure 92 — Calendrical history must separate astral-textual, monastic, epigraphic-almanac and ethnographic evidence before reconstructing a ritual year.	225
Figure 93 — A lunisolar ritual calendar coordinates lunar phases, solar position, astral reckoning and seasonal-local conditions; intercalation prevents unlimited drift between lunar months and the solar year.	227
Figure 94 — The ritual year contains overlapping seasonal, sectarian, household and recurrent observance cycles rather than one uniform sequence followed identically by everyone.	231
Figure 95 — Festival dates concentrate household labour, specialist services, market demand and use of public space, but the burdens and benefits are socially unequal.	232

Figure 96 — Life-cycle and mortuary history requires separate textual, archaeological and later-practice evidence streams before historical synthesis.	236
Figure 97 — Death unfolds as a social process involving the body, kin, disposal, property, specialists and subsequent memory rather than as a single ritual moment.	238
Figure 98 — The Vaiśālī relic tradition links cremation, Licchavi political claim, relic division and monumental commemoration while keeping textual memory and archaeology analytically distinct.	240
Figure 99 — Life-cycle rites connect persons and households to childhood, marriage, death, property, specialists and wider kin institutions, but their forms vary by chronology and community.	242
Figure 100 — Land grants: distinct evidence streams.	246
Figure 101 — The Bhagalpur plate: a bundle of agrarian and institutional rights.	247
Figure 102 — Selected regional land-grant nodes and documentary connections.	249
Figure 103 — Agrarian change through land grants: a controlled analytical model.	251
Figure 104 — Village, market and town: reciprocal flows.	256
Figure 105 — Regional nodes in the early medieval landscape.	258
Figure 106 — The haṭṭa as a rural–commercial interface.	259
Figure 107 — How to infer settlement hierarchy without overclaiming.	260
Figure 108 — Labour history: distinct evidence streams.	264
Figure 109 — A Pāla charter’s social and service field.	267
Figure 110 — Occupation depended on place and demand.	268
Figure 111 — From work to social group: a historical process.	270
Figure 112 — Social classification: distinct evidence streams.	272
Figure 113 — A Pāla charter addresses a social field, not a census.	276
Figure 114 — From social role to more bounded identity: possible pathways.	278
Figure 115 — Time-depth filter for using social labels.	279
Figure 116 — Brahmanical institutions: evidence before caste projection.	281
Figure 117 — How an early-medieval Brahman grantee was credentialed.	283
Figure 118 — Land, learning and authority: an institutional cycle.	286
Figure 119 — Chronology firewall: do not collapse different institutions.	283
Figure 120 — Panji history requires layered evidence.	291
Figure 121 — From lineage markers to matrimonial verification.	293
Figure 122 — Panji institutions changed over time.	294
Figure 123 — The Panji as a social-information network.	297
Figure 124 — Reconstructing women’s history requires layered evidence.	300
Figure 125 — Property is a bundle of distinct rights.	302
Figure 126 — Marriage links two kin networks without erasing separate property claims.	304
Figure 127 — A chronology firewall for women’s legal history.	306
Figure 128 — Karnata to Oiniwar: political periodisation and economic continuity.	309
Figure 129 — Agrarian surplus circulated through courts, markets, services and learned institutions.	311
Figure 130 — The 1324 rupture: separating political change from socio-economic persistence.	313
Figure 131 — Oiniwar-era court society as a distributed social-economic network.	314
Figure 132 — Political contact and social change, c. 1200–1550.	318
Figure 133 — Bidirectional migration and circulation around medieval Tirhut/Mithila.	319
Figure 134 — Channels through which new social worlds formed.	321
Figure 135 — Evidence firewall: conquest, migration, settlement and religious change.	324
Figure 136 — Persianate culture as a network rather than an ethnicity.	327

Figure 473 — The rural livelihood portfolio built around a small land base.	1046
Figure 474 — Creating economic scale through shared services and producer institutions without forcing ownership consolidation.	1048
Figure 475 — Land governance sequence from survey and record clarity to secure use, reorganisation and investment.	1050
Figure 476 — Circular migration as a repeated origin–destination system of labour, earnings, experience and return.	1052
Figure 477 — A migration-dependent household budget combines migrant earnings with farm, non-farm, public-support, credit and asset income.	1056
Figure 478 — Migration corridors segmented by distance, duration, skill and entry cost rather than one undifferentiated flow.	1056
Figure 479 — Portable protection for mobile workers requires linked identification, benefits, workplace protection, mobility assistance and return support.	1059
Figure 480 — Remittance transmission from destination earnings through transfer and household allocation to welfare, assets and local multipliers.	1063
Figure 481 — Remittance use as a household portfolio spanning survival, stabilisation, capability, assets and enterprise.	1065
Figure 482 — Incremental housing transformation from repair to service upgrades and diversified use.	1067
Figure 483 — Triangulating remittance, consumption and housing change requires several complementary evidence systems.	1070
Figure 484 — The education economy links household expenditure, learning services, mobility, credentials, local service demand and labour-market transition.	1073
Figure 485 — Coaching and educational migration operate through a spatial ladder from home and district towns to regional, national and global study hubs.	1075
Figure 486 — The true household cost of coaching migration includes mobility, exam, opportunity and risk costs in addition to tuition.	1076
Figure 487 — Studying and regulating the coaching economy requires administrative, household, examination, market, welfare and outcome evidence.	1081
Figure 488 — The health economy circulates household resources through care, financing, local markets, health labour and productive health outcomes.	1084
Figure 489 — Health access operates through a referral and mobility ladder, with bypassing when lower levels lack trusted services or diagnostics.	1085
Figure 490 — A health shock imposes indirect, access and long-term household costs in addition to the visible clinical bill.	1088
Figure 491 — Measuring a regional health economy requires household, facility, finance, market, workforce and outcome evidence together.	1090
Figure 492 — Effective connectivity is a chain linking the first mile, district nodes, trunk corridors and gateways; reliability and accessibility determine the economic reach of the network.	1093
Figure 493 — Major river crossings change economic distance by eliminating detours and opening new route combinations across the Kosi and Ganga.	1095
Figure 494 — Regional aviation expanded in successive layers: Darbhanga and Janakpur in 2020, major Darbhanga expansion from 2024, and Purnea commercial operations in 2025.	1099
Figure 495 — Connectivity must be measured with travel time, traffic, safety, resilience, aviation and economic-outcome data rather than infrastructure counts alone.	1101
Figure 496 — A digital payment depends on a chain of connectivity, identity, initiation, merchant acceptance and settlement; failure at any link can exclude the user.	1104
Figure 497 — Digital inclusion requires both reliable access and the capability to control, understand and contest transactions.	1104
Figure 498 — India–Nepal payment integration developed in distinct stages: merchant UPI acceptance in Nepal from 2024 and bilateral P2P UPI–NPI remittance from June 2026.	1110
Figure 499 — Platform economies coordinate customers, merchants and workers through software while redistributing costs, information and risk.	1108
Figure 500 — Visitor expenditure creates a local multiplier through linked transport, accommodation, experience, food, craft and service economies, but value can leak outside the destination.	1113

Figure 501 — Tourism and pilgrimage in Mithila–Vajji–Anga operate through overlapping cross-border, religious, heritage, cultural and ecological circuits rather than one linear route.	1115
Figure 502 — Pilgrimage economies move between ordinary demand, seasonal build-up, festival peaks and post-event costs; crowd capacity is therefore an economic variable.	1118
Figure 503 — Durable destination stewardship balances economic, physical, cultural and ecological capacity rather than maximising footfall alone.	1120
Figure 504 — Mithila painting moved from ritual surfaces into portable, national, international and digital markets without losing its older cultural meanings.	1122
Figure 505 — Direct sales, public portals, galleries, museums, digital platforms and souvenir channels distribute money, information and control differently.	1125
Figure 506 — Price formation depends on authorship, provenance, material qualities, recognition, originality and the market channel; there is no single “Mithila painting price”.	1127
Figure 507 — A durable global market requires economic fairness, cultural integrity, provenance and rights, and material preservation to reinforce one another.	1130
Figure 508 — Heritage identity, GI protection, copyright, marks, market branding and safeguarding are distinct but complementary layers.	1133
Figure 509 — A GI protects a qualifying origin-linked indication; it does not by itself monopolise techniques, guarantee producer income, or replace copyright.	1135
Figure 510 — Heritage branding creates durable producer value only when eligibility, traceability, market use, enforcement and benefit return form a functioning chain.	1137
Figure 511 — Intellectual-property rights are territorial even when Maithil cultural heritage and markets cross the India–Nepal border.	1140
Figure 512 — Agrarian climate risk emerges through a chain linking hazard, exposure, vulnerability, loss and response; adaptation changes the chain but cannot remove all residual risk.	1143
Figure 513 — Illustrative seasonal risk calendar: heat, water deficit and excess-water hazards overlap differently with rice, wheat, maize, livestock and water availability.	1144
Figure 514 — The 2025 Bihar–Madhesh warning: national or broad-regional rainfall totals must not be treated as farm-level water conditions; timing and local distribution drive crop-calendar risk.	1146
Figure 515 — Climate resilience is a portfolio: seed, calendar, water, soil, diversification, forecasts and finance must work around the farm household and its institutional access.	1149
Figure 516 — Flood resilience as a chain from monitoring and warning through protection, continuity, recovery and adaptation.	1153
Figure 517 — Flood resilience depends on a portfolio of structural protection, forecasting, drainage, emergency services, flood-storage landscapes and household finance.	1156
Figure 518 — Transboundary flood warning becomes useful only when upstream observation is converted into a trusted last-mile message and timely household action.	1154
Figure 519 — Adaptive basin governance treats every monsoon as new evidence for observing, anticipating, protecting, responding, recovering and revising the next plan.	1158
Figure 520 — Governance architecture of the post-federalisation India–Nepal border economy.	1160
Figure 521 — Infrastructure and policy milestones after Nepal’s federal transition.	1162
Figure 522 — Five cross-border flows that cannot be measured by customs data alone.	1164
Figure 523 — A producer- and household-centred dashboard for border-economy governance.	1167
Figure 524 — Family transformation as the interaction of demographic, economic, institutional and material change.	1170
Figure 525 — Household form, kinship network and resource network are analytically distinct.	1172
Figure 526 — Bihar and Madhesh provide different contemporary statistical baselines; definitions and dates must be kept visible.	1174
Figure 527 — A multi-local family circulates income, care, information and obligations across places.	1176
Figure 528 — Early marriage among women aged 20–24: Bihar trend and Nepal 2022 comparator; survey systems differ and are not one regional time series.	1179
Figure 529 — Marriage is a process involving search, eligibility, negotiation, ceremony, registration, residence and continuing kinship obligations.	1181
Figure 530 — Digitalisation widens the marriage search while education, work, caste/community, mobility and household strategy continue to filter matches.	1183
Figure 531 — Cross-border marriage joins one kinship relationship to distinct Indian and Nepali documentary and citizenship systems.	1185
Figure 532 — Bihar school GER by sex, 2024–25: girls exceed boys at each shown level, but absolute enrolment ratios fall sharply toward higher secondary.	1188

Figure 533 — AISHE 2023–24 estimated higher-education enrolment in Bihar: female enrolment (14.0 lakh) slightly exceeded male enrolment (13.6 lakh).....	1190
Figure 534 — Bihar PLFS 2025 labour-force participation, age 15+: a large male–female gap persists in both rural and urban areas despite educational gains.	1192
Figure 535 — From school access to economic agency: credentials must pass through mobility, job availability, care arrangements and social institutions before they become income and bargaining power.....	1195
Figure 536 — Bihar’s projected share of people aged 15–29 remains large but declines after 2021; projections are not new census counts.....	1198
Figure 537 — Bihar unemployment among people aged 15–29 in PLFS 2025: the urban youth rate is much higher than the rural rate under the same usual-status measure.	1199
Figure 538 — Rural Muzaffarpur youth, ASER 2023: high household smartphone access coexists with a large gender gap in personal ownership.....	1201
Figure 539 — Youth culture is produced through interacting institutions: education, work and migration, family and gender, media and consumption, language and locality, and public culture.	1202
Figure 540 — Social media and language form a feedback system: platform affordances shape visible forms, audience response and algorithmic selection, which feed back into community norms and everyday usage.....	1207
Figure 541 — Madhesh Province mother tongues in Census 2021: Maithili 41.73%, Bhojpuri 18.81%, Bajjika 18.44%, Nepali 5.76%, Tharu 4.17%, Urdu 4.08%, Tamang 1.65%, with the remainder grouped here as other languages.	1208
Figure 542 — India-wide Indic-language internet activities in the IAMAI–Kantar Internet in India Report 2024: video and music dominate, while social networking, shopping and search also occur substantially in Indic languages; these are not Bihar-specific estimates.	1209
Figure 543 — Different platform affordances affect different linguistic dimensions: typing and script choice, spoken registers, audiovisual performance, searchable spelling, algorithmic amplification and AI-assisted conversion.....	1211
Figure 544 — Public ritual operates as living infrastructure linking households, neighbourhoods, sacred sites, public institutions, media, migration and markets.	1216
Figure 545 — Madhesh Province religious affiliation in Nepal’s National Population and Housing Census 2021: Hindu 84.24%, Islam 13.28%, Buddhist 2.21%, Christian 0.18%, with the remaining reported religions grouped here as “Other”.....	1217
Figure 546 — Twenty-first-century public ritual is reshaped through interacting infrastructures: transport, migration, digital media, state capacity, environmental governance and markets.....	1220
Figure 547 — Evidence architecture for religious change: affiliation data must be combined with institutional records, ritual observation, media traces and historical comparison.	1222
Figure 548 — Contemporary caste is produced and contested across interacting institutions rather than operating as a single autonomous hierarchy.	1225
Figure 549 — Bihar Caste-Based Survey 2022–23: broad social categories as a share of the state population; rounded state-wide figures, not a direct map of Mithila, Vajji or Anga.....	1226
Figure 550 — Bihar survey poverty shares by broad social category; survey-defined poor means family monthly income up to ₹6,000, and the descriptive association is not a causal hierarchy.....	1227
Figure 551 — Madhesh Province housing quality by selected broad caste/ethnicity categories in Nepal’s NPHC 2021; the classifications are descriptive and are not equivalent to Bihar’s reservation categories.	1231
Figure 552 — Federalism as a three-tier social-citizenship architecture: rights and services become usable through coordination among federal, provincial and local institutions.....	1235
Figure 553 — Madhesh Province’s post-federal administrative field: eight districts, 136 local levels, 32 federal constituencies and 64 provincial first-past-the-post constituencies.	1237
Figure 554 — Legal identity becomes usable social citizenship through an administrative chain; each step can create access or exclusion.	1239
Figure 555 — Madhesh Province respondents reporting awareness of services provided by each level of government, 2022; awareness is not a measure of satisfaction or service quality.	1241
Figure 556 — Maithili, Angika and Bajjika occupy different recognition regimes in India/Bihar and Nepal/Madhesh; the categories are not directly interchangeable.	1244
Figure 557 — Madhesh Province mother-tongue shares in Census 2021; Angika is separately enumerated nationally but is not among the province’s leading mother tongues.	1246
Figure 558 — Analytical dashboard of institutional presence across census visibility, legal status, education, examinations, academics, broadcasting and provincial-language politics; it is not an official ranking.	1249
Figure 559 — Public-language equality depends on a chain from naming and legal status to institutional capacity, education, media and routine use; bottlenecks can occur at every stage.....	1252
Figure 560 — Heritage recognition is one stage in a living cultural cycle of practice, documentation, policy, reinterpretation and transmission.	1254

Figure 561 — Four regional examples show that safeguarding priorities differ by cultural form; visibility alone does not keep a practice alive.	1256
Figure 562 — Places, objects, knowledge, performance, language and livelihoods form one cultural ecosystem around communities of practice.	1255
Figure 563 — A living-culture dashboard evaluates transmission, participation, adaptability, livelihood, access, ecology, rights and documentation rather than publicity alone.	1260
Figure 564 — A regional cultural economy turns living practice into skills, rights, markets, income and reinvestment rather than treating visibility as the endpoint.	1263
Figure 565 — Local, tourism, digital and institutional markets offer different opportunities and leakage risks; shared infrastructure reduces dependence on any one channel.	1265
Figure 566 — Digital and AI tools can improve language creation, discovery, production and archives only when a provenance layer protects source, authorship, rights and edit history.	1267
Figure 567 — A 2026–2035 cultural-economy policy stack begins with living culture and builds skills, infrastructure, finance, markets, rights, cross-border cooperation and measurable accountability above it.	1269
Figure 568 — The <i>longue durée</i> of social change as cumulative transformation across major historical phases.	1273
Figure 569 — Social change emerges from interaction among ecology, households, land and labour, markets and mobility, state institutions, and language and culture.	1275
Figure 570 — Historical persistence usually works through reinvention under changing pressures rather than exact repetition.	1277
Figure 571 — India and Nepal remain different political economies within a cross-border social interaction zone.	1278
Figure 572 — Market integration as layered expansion from household provisioning to wider regional, national, cross-border and digital exchange.	1282
Figure 573 — Contemporary households combine production, wage work, enterprise, migration, education, savings and credit as a portfolio economy.	1285
Figure 574 — Infrastructure and institutions can lower transaction costs and widen access, while monopoly, debt, weak storage and exclusion can concentrate market power.	1286
Figure 575 — Market integration transmits both opportunity and shock; resilience depends on diversified income, storage, insurance, networks, public support and remittances.	1287
Figure 576 — The household is a changing institution connecting property, kinship, labour, care and social reproduction.	1291
Figure 577 — Caste, class and gender operate through distinct but interacting mechanisms, mediated by institutions.	1293
Figure 578 — Contemporary households are often multi-local networks linking origin, regional centres, migration destinations and digital-financial space.	1295
Figure 579 — Across time, persistent questions of ownership, labour, care, marriage, mobility and claims are answered through changing institutions.	1298
Figure 580 — Riverine ecology functions as economic infrastructure through soils, wetlands, settlement, mobility, markets and public works.	1300
Figure 581 — Floodplain economies follow a seasonal calendar in which risk, production and recovery are intertwined.	1302
Figure 582 — River engineering can reduce frequent losses while redistributing drainage, maintenance and breach risk.	1304
Figure 583 — Adaptive river governance combines forecasts, land-use decisions, livelihood diversity, maintained infrastructure, finance, cross-border coordination and ecological functions.	1306
Figure 584 — Language acts as shared infrastructure across household, education, public institutions, markets, media and digital systems.	1308
Figure 585 — Language infrastructure accumulates across oral, manuscript, print, broadcast and networked digital media.	1310
Figure 586 — Formal recognition becomes usable public access only when content, interfaces, comprehension and service outcomes align.	1311
Figure 587 — Digital language capability depends on encoding, corpora, speech tools, platforms, archives and governance working together.	1313
Figure 588 — One interaction zone can contain dense mobility and exchange while India and Nepal retain distinct political-economic institutions.	1316
Figure 589 — Selected institutional and infrastructure milestones have progressively changed the cost and form of India–Nepal exchange.	1318
Figure 590 — Labour, goods, energy and money cross the same border through different institutional channels.	1320
Figure 591 — Cross-border resilience depends on whether information, infrastructure and household adaptation outrun the transmission of shocks.	1321
Figure 592 — Cultural persistence operates through repeated cycles of practice, transmission, institutionalisation, reinterpretation and reproduction.	1325
Figure 593 — Cultural continuity is mediated by an ecology of household, associative, educational, cultural, state and market institutions.	1327

Figure 594 — Institutionalisation selects, documents, authorises and circulates culture, with consequences that should return to practitioners.	1328
Figure 595 — Cultural safeguarding should be measured through continuity, adaptation, access, livelihoods, documentation and institutional health.	1330
Figure 596 — A method for writing regional history without treating continuity as a timeless essence.	1333
Figure 597 — Mithila, Vajji and Anga are best reconstructed across interacting ecological, household, market, political, linguistic and cultural scales.	1335
Figure 598 — Long continuities and major transformations coexist across land, household, hierarchy, language, culture and economy.	1337
Figure 599 — Final interpretive framework: locate evidence, periodise categories, trace institutions, test distribution, compare scales, explain change and retain uncertainty.	1339

PART I

**LAND, ENVIRONMENT AND THE
MAKING OF HUMAN LANDSCAPES**

Chapters 1–5

Chapter 1 — The Physical Foundations of Society

The socio-cultural and economic history of Mithila, Vajji and Anga begins with landscape, but not with environmental determinism. Rivers, soils, forests, monsoon rhythms, wetlands, seismicity and routes created changing fields of possibility. They affected where settlement was easy or difficult, which crops could be sustained, how goods moved, where towns acquired strategic advantages, and why households repeatedly had to adapt to flood, erosion, drought, sedimentation and earthquake. None of those environmental conditions, however, produced a single inevitable political or cultural outcome. Human institutions mediated them. This chapter therefore treats physical geography as historical infrastructure: durable enough to shape recurring problems and opportunities, but dynamic enough to prevent the historian from treating any river course, floodplain edge or ecological boundary as timeless.

1.1 Historical geography as evidence, not destiny

Historical regions do not arrive with permanently surveyed natural borders. “Mithila,” “Videha,” “Vajji,” “Anga,” “Tirhut,” “Madhesh” and “Tarai” belong to different chronological and documentary contexts. Their spatial relationships changed with political authority, settlement, language, pilgrimage, transport and administration. Modern districts are useful for locating archaeological sites, soils and hydrological data, but they cannot simply be projected backward. The physical landscape is therefore used here as a frame for asking where movement, settlement, cultivation and exchange were possible, not as a device for drawing ancient borders from modern rivers.

This distinction is especially important in the Gangetic plains because rivers themselves migrate. The Eastern Gangetic Plains are characterized by shallow, aggrading channels, frequent avulsion and extensive flooding, while river systems differ substantially in sediment load and hydrological regime (Sinha et al. 2005). A settlement described in relation to a channel two millennia ago cannot automatically be located by assuming that the channel occupied its present course. Floodplain history is, in part, a history of moving reference points.

The same caution applies to ecological labels. The Tarai of Nepal is a physiographic piedmont plain made of recent and post-Pleistocene alluvial deposits south of the Churia region, but modern administrative “Madhesh” is a political and social formation with a different history. Likewise, the southern and eastern landscapes associated with Anga include Ganga alluvium as well as hill-margin and older-rock environments toward Banka and Munger. The study region is best understood as an interconnected environmental transect rather than a single uniform plain.

1.2 From Himalayan headwaters to the Gangetic plain

The most consequential physical relationship in northern Mithila is vertical as much as horizontal. Himalayan and middle-hill catchments gather monsoon rainfall and, in some basins, snow- and glacier-fed runoff; rivers descend through confined valleys, cross the Churia/Siwalik belt and then lose gradient abruptly on entering the Tarai and Gangetic foreland. Water and sediment that are tightly confined upstream spread across a very low-relief alluvial surface downstream. The result is not merely a river flowing from north to south. It is a linked mountain–piedmont–plain system in which rainfall, slope, sediment production and channel mobility are transferred across the India–Nepal border.

Nepal’s Forest Research and Training Centre describes the Terai physiographic region as a gently sloping piedmont plain of recent and post-Pleistocene alluvium between the Churia to the north and the Indian Gangetic plain to the south. This formulation is useful historically because it emphasizes continuity of

landform across a modern international boundary (FRTC 2022). The frontier has enormous political importance, but water, sediment, groundwater and ecological processes cross it.

The Himalaya–Tarai–plain gradient also created differentiated resource zones. Timber, forest produce, stone, grazing and upland products could move downslope; grain, salt, textiles and manufactured goods could move in several directions; rivers and foothill tracks could alternately facilitate and obstruct travel. Later chapters will test these possibilities against period-specific evidence rather than assuming a permanent trade system.

Not to scale. The historical regions overlap these environments but are not identical to them.

Figure 1 — A generalized Himalaya–Tarai–Gangetic plain–Anga environmental transect (colour schematic).

1.3 The Himalayan foreland basin and the making of alluvium

The Gangetic plain north of the peninsular uplands forms part of the Himalayan foreland basin, a long-lived zone of subsidence and sediment accumulation generated by the tectonic loading of the rising Himalaya. For social history, the crucial fact is not the geological mechanism by itself but its consequence: very thick Quaternary alluvium, low gradients and a surface continually reworked by rivers. Sinha and colleagues distinguish the Eastern Gangetic Plains by widespread aggradation, shallow channels and avulsion, characteristics that help explain why “stable” agricultural land may be locally fertile yet historically vulnerable to channel change (Sinha et al. 2005).

The Gandak and Kosi systems have built major megafan forms in the plains. The Gandak megafan preserves a complex history of river migration, soils and tectonic tilting; Mohindra, Parkash and Prasad (1992) used soil development to reconstruct surfaces of different ages and argued for major eastward shifting of the Gandak through the late Quaternary and Holocene. Later work has refined the tectonic and depositional picture, but the historical implication remains: soils and settlement surfaces are not all the same age even when they appear today as one continuous plain.

This dynamic alluvial architecture complicates archaeological preservation. Sites may be buried by sediment, eroded by migrating channels, isolated on older interfluvies or obscured by modern cultivation. Absence of visible surface remains in a floodplain cannot therefore be equated automatically with absence of past occupation. Archaeology in such a landscape must work with geomorphology.

1.4 The Ganga as trunk river and historical corridor

The Ganga cuts across the broader study region from west to east and separates much of the north-Bihar alluvial domain from the older uplands and south-bank plains associated with parts of Anga and Munger. It is simultaneously a drainage trunk, a floodplain-maker, a transport route, a source of fish and fertile silt, a ritual landscape and a boundary that has been crossed repeatedly. These functions were never identical in all periods. Navigation, ferrying, pilgrimage, taxation, military movement and commodity traffic each depended on technologies, political control and seasonal water levels.

The river also connects rather than merely divides. Himalayan tributaries deliver water and sediment to it from the north; hill and plateau-margin streams enter from the south and southeast. Bhagalpur's modern hydrogeological profile, for example, identifies the Ganga along with Kosi, Chandan and several smaller drainages across a landscape combining Indo-Gangetic alluvium with marginal alluvial tracts (Central Ground Water Board 2013a). That juxtaposition captures a central theme of Anga's physical history: Ganga-connected lowlands alongside routes toward older uplands.

Because the Ganga's bars, diaras, banks and channels are mobile, river-edge settlement is a negotiated geography. Fertility and connectivity may coexist with erosion and displacement. Later chapters on Champa, Bhagalpur, river commerce and pilgrimage will therefore treat the Ganga as an active historical process, not merely a line on a map.

1.5 Gandak / Narayani: a trans-Himalayan-to-plain system

The Narayani–Gandak system demonstrates the scale mismatch between mountain catchments and plain landscapes. Nepal's National Water Plan describes the Narayani basin as a major Himalayan drainage with tributaries including the Trishuli, Budhi Gandaki, Marsyangdi, Seti and Kali Gandaki. Downstream, the Gandak debouches onto the middle Gangetic plain and has constructed a large megafan in eastern Uttar Pradesh and northwestern Bihar (Government of Nepal, National Water Plan; Mohindra, Parkash and Prasad 1992).

The historical importance of such a system lies in repeated transfers: water from the Himalaya, sediment from rapidly eroding mountain terrain, routes that connect valleys to the plains, and flood risks that are experienced far from the sites of sediment production. The fan surface contains palaeochannels, oxbows, tals and soils of differing ages. These are archives of former river positions and, potentially, of changing settlement opportunity.

For Mithila and Vajji history, the Gandak is also a caution against treating a river as a fixed cultural frontier. A channel with a long record of migration may function as a political boundary in one period and as an internal corridor in another. Boundary claims must therefore be demonstrated textually and historically rather than inferred from physical geography alone.

1.6 Bagmati, Kamla and the interfan plains

Between the large Gandak and Kosi fan systems lie plains drained by rivers such as the Bagmati and Kamla. They are often less visually dramatic than the Kosi, but they are no less important to settlement history. Jain and Sinha's work on the Bagmati shows a highly dynamic anabranching river with repeated avulsion, overbank flooding, high suspended load and sensitivity to both sedimentological adjustment and tectonic tilting (Jain and Sinha 2004; 2005).

The Bagmati example matters methodologically. It demonstrates that instability in north Bihar is not limited to one "sorrowful" river. Interfan channels can also shift rapidly, create abandoned courses,

redistribute waterlogging and alter local gradients. Villages, roads, tanks, fields and administrative boundaries have repeatedly had to coexist with this mobility.

The Kamla and other foothill-fed systems belong to the same broad problem of low-gradient passage from Nepal into north Bihar. Their local histories differ, and no single fluvial model should be imposed on all of them. What they share is the capacity to transform cultivated space seasonally and episodically, linking agrarian opportunity to hydrological uncertainty.

Figure 2 — Schematic drainage architecture of the study region (colour; not to scale).

1.7 The Kosi: megafan, sediment and avulsion

The Kosi is the clearest example of why geomorphology belongs inside social and economic history. Its basin links high Himalayan catchments, middle-hill tributaries, the Nepal plains and a vast alluvial fan in north Bihar. Sinha and colleagues' basin-scale analysis emphasizes the large sediment flux delivered to the foreland and identifies sediment dynamics as a central management problem connected with channel instability and flooding (Sinha et al. 2019).

Older popular narratives often described the Kosi as having migrated more than one hundred kilometres steadily westward over roughly two centuries. Chakraborty and colleagues re-examined historical maps and surface deposits and argued that the record is more complicated: oscillatory channel movement and nodal avulsion better fit much of the evidence than a simple, continuous westward sweep (Chakraborty et al. 2010). That revision is a useful lesson for this volume: even apparently familiar environmental histories require source criticism.

The 2008 avulsion, discussed fully in the companion political-environmental volume and later in this volume's chapter on river-development projects, showed how embankments, aggradation, maintenance, channel geometry and extreme flow can combine to produce catastrophic displacement. Here the point is more basic. The Kosi megafan is a productive agricultural landscape created by sediment and at the same time a landscape in which sediment can raise channels, bury fields, create new surfaces and redirect water. Fertility and hazard are products of the same fluvial system.

1.8 Mahananda and the eastern floodplain transition

East of the Kosi domain, the Mahananda and associated channels occupy a transition toward Bengal. Modern soil-landform work in Katihar identifies old alluvial plains, young alluvial plains, meander plains, active floodplains and char/point-bar environments, underscoring the fine-grained heterogeneity of what a small-scale map might simply label “alluvium” (Reza et al. 2022).

This heterogeneity matters for both agriculture and communication. Young sandy surfaces, silty floodplains, abandoned meanders and older, more stable tracts offer different combinations of drainage, soil development and flood exposure. Historical settlement density cannot be interpreted responsibly without attention to such local differences.

The eastern floodplain is also where the study region opens toward Bengal’s riverine world. That connection will become crucial for Champa, Bhagalpur, colonial commodity circulation, jute, migration and later rail and road networks. Physical geography created corridors; historical institutions determined how intensively they were used.

1.9 Anga’s southern and southeastern landscapes

Anga cannot be reduced to a north-Bihar floodplain model. The historical core around Champa/Bhagalpur is tied to the Ganga, but the wider eastern Bihar landscape grades southward toward older rocks, hill tracts and plateau-margin drainage. Modern Bhagalpur combines flat Indo-Gangetic alluvium and marginal alluvial tracts, while Banka rises toward hilly country adjoining Jharkhand and is drained by rivers such as the Chandan/Chanan, Badua and other hill streams (Central Ground Water Board 2013a; Census of India 2011, Banka District Census Handbook).

The Chandan rises in the uplands south of Bihar and flows northward toward the Ganga through Banka and Bhagalpur. Such south-to-north drainage creates a different environmental relation from the Himalayan rivers: seasonal hill streams carry water and sand from the plateau margin into the Ganga corridor. Modern district sources describe broad fertile northern plains but hilly and forested southern tracts in Banka, a contrast that would have affected cultivation, forest use, transport and settlement density.

Munger adds another environmental edge. The Central Ground Water Board describes rocky uplands and the Kharagpur Hill tract alongside pediplains and Ganga alluvium, with the river along the northern margin (Central Ground Water Board 2013b). The resulting socio-economic history is therefore one of interfaces: riverine lowland, older alluvium, rocky upland, forest resources and routes toward the Chota Nagpur plateau.

1.10 Soils: fertility, variability and the danger of a single “Gangetic soil”

The image of the Gangetic plain as uniformly fertile is useful only at the broadest scale. Alluvial soils vary by age, texture, drainage, sediment source, groundwater conditions and landform position. Bihar’s official agro-climatic classification distinguishes north-western and north-eastern alluvial zones from the southern alluvial zone, with differences in texture, rainfall and cropping possibilities (Government of Bihar 2019).

The north-western alluvial zone is described mainly as sandy loam to loam; the north-east includes sandy loam and clay loam with higher mean rainfall; south Bihar combines sandy loam, clay loam, loam and clay. These categories are modern agronomic summaries, not timeless soil maps, but they illustrate why agrarian history must be local. A crop regime successful on a better-drained older surface may fail in a waterlogged depression only a few kilometres away.

Floodplain soil is also historically renewed. Sediment deposition can replenish nutrients while simultaneously burying standing crops, property boundaries and infrastructure. Sand casting can turn former cultivated land into a low-productivity surface for years. Conversely, stable flood recession can produce highly productive seasonal fields. The same process may therefore appear as “fertility” in a long-run regional description and as disaster in household history.

1.11 Monsoon seasonality and the agricultural calendar

Monsoon timing provides one of the strongest recurring seasonal structures in regional history. Bihar receives most of its rainfall during the southwest monsoon, with official state summaries placing the principal rainy season from roughly mid-June through September. Agro-climatic means are higher in the north-east than in south Bihar, but annual and district variation is large (Government of Bihar 2019; Directorate of Economics and Statistics, Bihar).

The historical consequences extend beyond crop choice. Monsoon onset affects sowing, road conditions, ferry reliability, disease environments, fodder, fishing and labour demand. High water may expand river transport while cutting terrestrial routes. A delayed monsoon can produce water stress even in a region famous for floods. An intense monsoon can destroy crops through waterlogging or river breach. “Wet” and “dry” are therefore insufficient social categories; timing, duration and spatial distribution matter.

Climate is not stationary. The long-term history of rainfall variability and contemporary anthropogenic climate change will be treated in later chapters with period-appropriate data. This chapter uses modern climatology to establish the seasonal framework only; it does not project twentieth- or twenty-first-century rainfall averages unchanged into prehistory or antiquity.

Figure 3 — Indicative rainfall contrast among Bihar agro-climatic zones (colour chart).

1.12 Wetlands, oxbows, tals and chaurs

North Bihar’s low relief and mobile rivers have produced abundant floodplain wetlands, abandoned channels, oxbows, marshes and shallow depressions. Singh and Sinha show that many wetlands in the Kosi–

Ganga interfluve are products of fluvial scouring, channel abandonment and later cut-and-fill processes (Singh and Sinha 2020). They are therefore not residual “unused” spaces but part of the river system itself.

Wetlands can store floodwater, support fish and aquatic vegetation, provide seasonal grazing and cultivation, and maintain local hydrological connectivity. Kabartal/Kanwar Jheel, now a Ramsar site, is one modern example of a larger north-Bihar floodplain complex; its contemporary ecological status should not be projected backward, but it demonstrates the continued importance of wetland mosaics in an intensively cultivated plain.

For social history, wetlands complicate land categories. A depression may be open water in the monsoon, marsh in one season, fishing ground in another and cultivated land when dry. Property, access rights and occupational specialization may therefore vary with water level. Later chapters on fisheries, makhana, agrarian society and rural commons will return to this seasonal multiplicity.

1.13 Flood, avulsion, erosion and deposition as different processes

Flood history requires precise vocabulary. Overbank inundation, embankment breach, bank erosion and avulsion are related but not identical. A river may flood while staying in its channel belt; it may erode one bank without abandoning the channel; or it may avulse and establish a new course. These processes have different implications for settlement, property and recovery. Treating them all as a generic “flood” obscures causation.

Bagmati studies show repeated channel migration and avulsion in an interfan setting, while Kosi research demonstrates how sediment accumulation and channel configuration interact with avulsion risk (Jain and Sinha 2004; Sinha et al. 2019). Such findings are not a substitute for historical sources, but they help historians interpret why old channels, abandoned levees and sudden shifts recur in maps and settlement memory.

Erosion and deposition also redistribute wealth. Land lost to a river may reappear elsewhere as char or diara; access to newly formed land can become contested. Sand deposition may ruin one field while silt deposition benefits another. Public works such as embankments, canals and drainage schemes redistribute these processes rather than abolishing them. That political ecology will become central in the modern chapters.

1.14 Earthquakes and the tectonic setting

The plains appear flat and quiet, but they lie beside an active Himalayan plate boundary and above subsurface structures capable of influencing river gradients. Jain and Sinha identified geomorphic anomalies in the Bagmati plains consistent with active tectonic deformation, while twentieth-century earthquakes demonstrated the region’s direct seismic vulnerability (Jain and Sinha 2005).

The 15 January 1934 Bihar–Nepal earthquake is catalogued by the USGS/ISC-GEM system at magnitude 8.0. Its effects belong to modern disaster history, but the event also reminds the historian that built environments, water systems and settlement hierarchies can be abruptly transformed by forces invisible in ordinary annual cycles. Earlier earthquakes are more difficult to reconstruct and require careful separation of geological, archaeological and textual evidence.

It would be a mistake, however, to explain every river shift through tectonics. Hydrology, sediment load, bank material, local slope and human intervention also matter. The methodological lesson is multicausality: tectonics is one control among several.

1.15 Forests, grasslands and ecological edges

The modern cultivated plain can conceal the historical importance of forests and grasslands. The Himalayan foothills and Churia–Tarai belt supported extensive forest environments; southern Banka and the Kharagpur hills likewise connect the study region to upland forest resources. Modern forest reports cannot reconstruct ancient vegetation directly, but they identify enduring ecological contrasts that shaped possibilities for timber, fuel, fodder, wild foods, hunting and shifting settlement fronts.

Forest clearance is a historical process, not a one-time transition from “nature” to “agriculture.” Different periods experienced expansion and contraction of cultivation, state claims over forest, disease environments, market demand and transport access. The Nepal Tarai, in particular, underwent major twentieth-century transformations through forest clearance, malaria control and migration; those developments will be treated later rather than projected into earlier centuries.

Edges between forest, wetland and field also supported specialized livelihoods. Fishing, pastoralism, gathering, boat work, seasonal cultivation and craft production often depended on access to more than one ecological zone. A social history organized only around permanent plough agriculture would miss these mixed economies.

1.16 Routes, mobility and the geography of exchange

Physical geography shaped route choice without dictating a single permanent network. The Ganga offered longitudinal movement; north–south rivers and foothill corridors linked the plains to Nepal; upland-margin streams and passes connected Anga toward the plateau and Bengal. In the dry season, carts and foot traffic could use surfaces that became difficult during the rains. Ferries turned river crossings into nodal points. Towns benefited when political authority, markets and routes coincided.

The same river could be route and obstacle. High water may facilitate boats yet interrupt land traffic; a shifted channel may strand an old landing place; sedimentation can change navigability. Historical trade claims must therefore be tied to evidence such as itineraries, inscriptions, administrative records, archaeological distributions or documented markets. A modern road parallel to an old river does not prove an ancient route.

This caution is especially relevant for discussions of Vaishali, Janakpur and Champa. Their historical importance cannot be derived from geography alone, but geography helps explain why certain locations repeatedly became attractive when institutions capable of organizing exchange emerged.

1.17 Environment, household economy and unequal risk

Environmental events are socially selective. A flood of the same depth affects a landowner with savings, a tenant farmer, a fisher, a landless labourer and a household with livestock in different ways. Access to raised ground, boats, credit, roads, embankments, drainage and state relief converts a physical hazard into unequal social outcomes. Gender and caste can shape mobility, asset ownership and access to compensation. These mechanisms belong to later periods where evidence is available, but the conceptual distinction is essential from the outset.

Likewise, “fertile alluvium” is not a social condition. Fertility becomes livelihood through land access, labour, seed, irrigation, livestock, markets and political rights. “River connectivity” becomes commerce only when boats, security, exchange institutions and demand exist. The physical foundation is therefore necessary but never sufficient.

The volume will repeatedly return to this distinction between environmental capacity and institutional realization. It prevents the familiar mistake of turning geography into destiny while still taking geography seriously.

1.18 Methodological implications for the rest of Volume II

Five rules follow from this chapter. First, historical regions must be mapped by period, not by a single modern outline. Second, rivers should be treated as mobile systems; historical place identification must allow for palaeochannels and avulsion. Third, modern climatology and soil classification can explain processes but cannot be projected unchanged into deep time. Fourth, hazards must be distinguished—flooding, breach, erosion, waterlogging, drought and earthquake produce different social consequences. Fifth, environment must be connected to institutions before socio-economic conclusions are drawn.

These rules shape the chapters that follow. Prehistoric settlement will be read against changing landforms and preservation conditions. Early urbanisation will be studied in relation to rivers and agrarian surplus without assuming that rivers alone produced cities. Agrarian chapters will distinguish soil potential from landholding systems. Trade chapters will separate possible corridors from demonstrated exchange. Flood and development chapters will distinguish natural processes from infrastructures that redistribute risk.

The result should be a regional history that is materially grounded but not reductionist: one in which the Himalaya, Tarai, Gangetic plains, Ganga corridor, wetlands and Anga uplands form changing environmental infrastructures for human action.

1.19 Comparative landscape table

Table 1.1 — Comparative landscape table

Landscape zone	Historical opportunities	Recurring constraints	Evidence needed before historical inference
Himalayan / hill catchments	Water, forest products, stone, routes to valleys	Steep terrain, landslides, seasonal access	Period-specific route, settlement and exchange evidence
Tarai / piedmont	Forest, grazing, groundwater, cross-border corridors	Waterlogging, disease environments, river migration	Archaeology, historical ecology, land and administrative records
North Bihar alluvial plains	Intensive cultivation, wetlands, river routes, dense settlement potential	Flooding, avulsion, erosion, drainage congestion	Geomorphology plus settlement, landholding and market evidence
Ganga corridor	East–west transport, fisheries, pilgrimage, alluvial agriculture	Bank erosion, channel migration, crossing costs	Navigation, ferry, market, archaeological and textual evidence
Anga alluvial–upland interface	River commerce plus forest/upland resources and plateau links	Seasonal streams, uneven soils, hill–plain access	Local archaeology, route evidence, district geology and historical records

Conclusion

The physical foundations of Mithila, Vajji and Anga are plural. North of the Ganga, Himalayan and foothill rivers build and rebuild a low-gradient alluvial plain in which fertile soils, wetlands, seasonal water and recurring channel instability coexist. South and southeast of the Ganga, the Anga landscape adds older alluvium, hill streams, rocky uplands and routes toward the plateau. Across Nepal and India, the Tarai and Gangetic plain form an environmental continuum crossed by a modern state boundary whose political importance does not interrupt hydrological process.

That continuity must not be confused with cultural or political unity. Environmental connection creates possibilities for movement and exchange; it does not prove a common polity, language or identity. Conversely, political boundaries can be historically powerful even where rivers and ecological systems cross them. The central methodological task of Volume II is therefore to connect physical process to social evidence without allowing one to substitute for the other.

Chapter 2 — Prehistoric Settlement and Subsistence

Prehistory in the Mithila–Vajji–Anga study region cannot be written as the early chapter of a community whose later name is already known. The archaeological record precedes the historical identities, states, literary languages and social classifications that dominate later periods. Accordingly, this chapter asks a narrower but more defensible set of questions: where are prehistoric occupations actually documented; what kinds of settlement and subsistence can be reconstructed from stratified evidence; what remains uncertain because alluvial processes have buried, eroded or displaced sites; and which wider Middle Ganga or Himalayan comparisons illuminate the problem without becoming substitutes for local evidence. The principal direct anchors used here are the Patu/Rato Khola lithic complex in eastern Nepal, Chechar–Kutubpur in present Vaishali district, and Chirand in north Bihar. Wider sites such as Lahuradewa and Senuwar are used comparatively and are labelled as such.

2.1 Prehistory without retrospective identities

Terms such as Mithila, Videha, Vajji and Anga belong to historical geographies whose documentary visibility is much later than the Stone Age occupations considered here. A lithic scatter in the Siwalik foothills is not evidence of an early ‘Maithil’ population, and a Neolithic settlement in modern Vaishali district is not automatically a settlement of the later Vajjian republic. Modern political borders are equally anachronistic as cultural boundaries for the early Holocene. The historian may use present district and national names to locate evidence, but those labels describe where the site is now, not who prehistoric inhabitants believed themselves to be.

This distinction is more than terminological caution. It changes the kinds of conclusions that can responsibly be drawn. Archaeology can reconstruct technologies, diets, settlement forms, seasonality, environmental choices and sometimes exchange or mobility. It is usually much less secure for language, ethnicity, caste, political identity or named religious affiliation in periods without writing. Those later categories will enter this volume only when the evidence capable of supporting them appears.

2.2 The evidence problem of an alluvial country

The north-Bihar plain is a difficult archive. The rivers described in Chapter 1 have repeatedly migrated, aggraded, incised and reworked their floodplains. A prehistoric occupation surface may be sealed beneath metres of younger sediment, truncated by a later channel, exposed only briefly on an eroding bank, or

destroyed by agriculture and construction. Consequently, low site counts in an actively alluviating zone cannot be translated directly into low prehistoric population. Archaeological visibility is partly a geomorphological outcome.

The contrast with foothill terraces is instructive. In the Siwaliks, artefacts may survive on older terrace surfaces or within soils that can be related to Quaternary landforms; on a young floodplain, equivalent occupations may be deeply buried or displaced. This asymmetry helps explain why the prehistoric record of Nepal's Siwalik margins and the excavated river-bank mounds of Bihar looks discontinuous even though human use of the wider landscape need not have been discontinuous.

2.3 An evidence hierarchy for Chapter 2

The strongest claims in this chapter rest on excavated or closely contextualized material: stratigraphic position, structures, radiometric samples, lithic assemblages, pottery, bone and antler objects, botanical remains and faunal remains. A second level consists of inferences repeated across more than one secure context—for example, the association of wattle-and-daub architecture with settled or recurrent occupation. A third level uses wider regional comparisons, such as the archaeobotany of the Middle Ganga Plain, to frame questions that local excavation has not yet answered. The chapter does not use later literary traditions as evidence for prehistoric settlement.

This hierarchy is particularly important for chronology. The category 'Neolithic' is not a single date shared across South Asia. Local sequences differ; published radiocarbon determinations may be internally inconsistent; old excavations did not always use present sampling protocols; and technological traits can persist across chronological boundaries. Dates are therefore presented as ranges or as the published assessment of a particular context, not as a universal timetable.

Chapter 2 uses the upper three levels; the fourth is explicitly rejected.

Figure 4 — Evidence control for prehistoric reconstruction: direct context, supported inference, comparison, and rejected retrojection (colour schematic).

2.4 Eastern Nepal: the Patu / Rato Khola prehistoric record

The most important prehistoric evidence close to the Nepal side of the later Mithila region comes from the Siwalik foothills of Mahottari district. Gudrun Corvinus's surveys at Patu and along the Rato Khola established a large cobble-tool industry associated with older river terraces. The Patu 2 locality was described as a particularly dense concentration or activity area. The assemblage includes abundant flakes, choppers, core-scrapers and adze- or axe-like tools made largely from locally available cobbles. Corvinus's work is foundational because it connects artefacts to terrace geomorphology rather than treating isolated stone tools as self-dating objects (Corvinus 1987, 1989, 2007).

Later synthesis has emphasized that Patu is best understood in a Late Pleistocene–Early Holocene sub-Himalayan context rather than forced into an old, uniform 'Lower Palaeolithic chopper' category. Gaillard, Singh and Dambricourt-Malassé describe the Patu assemblage as a macrolithic industry with strong flake representation, unifacial and bifacial adze-like pieces, choppers and core-scrapers; a charcoal sample from the artefact-bearing horizon yielded an age around 7 ka BP and therefore a minimum age for the industry. The chronology is early Holocene, but the industry is not evidence for farming. It is evidence for human occupation and technological adaptation in a forested, stream-rich foothill environment (Gaillard, Singh and Dambricourt-Malassé 2011).

This matters to the history of the Nepal–India borderland in a negative as well as a positive sense. It demonstrates prehistoric human use of landscapes north of the present international boundary, while offering no basis for assigning those people to later Videha, Maithili, Madhesi or other identities. The archaeological continuity to be investigated is therefore occupation of an ecological corridor, not continuity of a named community.

2.5 Palaeolithic and Mesolithic labels: why terminology must remain provisional

Older South Asian prehistory often classified stone-tool industries primarily by typology. In the Siwaliks this produced long debates around 'Soanian', Acheulean, chopper-chopping and later macrolithic assemblages. Modern work gives greater weight to geological surface, stratigraphy, raw-material economy, reduction sequence and absolute dating. Patu is a good example of why the change matters: cobble tools alone do not make an assemblage ancient, and similar tool forms can recur when local river cobbles encourage comparable technical solutions.

For this volume, therefore, the labels Palaeolithic, Mesolithic and Neolithic are used as archaeological conveniences tied to the cited literature, not as rigid social stages. 'Mesolithic' at Patu describes a scholarly placement of a lithic tradition; it does not imply that the inhabitants followed the same subsistence regime as every other Mesolithic community in South Asia. Likewise, 'Neolithic' at Chirand and Chechar–Kutubpur refers to archaeological packages in which settled life, food production and characteristic material technologies become visible; it does not mean that foraging suddenly ceased.

2.6 North Bihar's strongest Neolithic anchors

Within Bihar, the excavated Neolithic record most relevant to the northern alluvial plain is concentrated at Chirand in Saran and Chechar–Kutubpur in Vaishali. They are not interchangeable. Chirand has a long excavation history, a thick Neolithic deposit and unusually rich bone and antler industries together with plant and animal remains. Chechar–Kutubpur is geographically closer to the later Vaishali–Vajji core and

therefore crucial for this book, but the excavated exposure was smaller and the published evidence is correspondingly more limited. The strength of the chapter lies in keeping those evidentiary differences visible.

Other Bihar sites such as Senuwar and Taradih are indispensable for understanding the broader Neolithic of Bihar, but they lie outside the principal north-bank Mithila–Vajji focus. They are used here to test regional models, not to fill local gaps. In the Anga/Bhagalpur zone, excavated sequences at Oriup and Champa become especially informative from Chalcolithic and later horizons; those belong to Chapter 3 and are not pulled backward to manufacture a Neolithic Anga story.

Figure 5 — Selected prehistoric anchors used in Chapter 2: direct study-zone evidence and explicitly labelled regional comparators (colour schematic; not to scale).

2.7 Chirand: a durable settlement on a riverine margin

Chirand lies on a major riverine corridor in north Bihar, near the Ganga–Ghaghara system. Excavation revealed a substantial Neolithic occupation underlying later cultural periods. B. S. Verma’s early reports emphasized the thickness of the Neolithic stratum and the variety of bone, antler, stone and ceramic materials. The site therefore provides something rare in the alluvial plain: not an isolated implement but a repeated occupation sequence in which architecture, tools and subsistence remains can be read together (Verma 1971; Verma 2007).

The settlement evidence includes post-holes, reed or bamboo impressions in burnt clay, rammed floors and circular or semicircular wattle-and-daub structures. These are lightweight technologies, but lightweight does not mean temporary. Mud, reed and bamboo are rational building materials in an alluvial environment where timber and grasses are available and heavy masonry is unnecessary for domestic structures. Rebuilding may have been frequent; the archaeological signature of repeated rebuilding is part of settled life rather than evidence against it.

2.8 Chirand's bone, antler and stone technologies

One of Chirand's most distinctive archaeological contributions is the scale and variety of its osseous industry. Excavators reported celts, scrapers, chisels, hammers, needles, points, borers, awls, diggers, pins, arrowheads and ornaments made from bone, antler, ivory and shell. The significance lies not simply in the list of objects. Manufacture required selection of suitable skeletal elements, cutting, scraping, grinding, perforation and finishing. Unfinished pieces indicate that at least some production took place within the settlement rather than all objects arriving ready-made (Verma 1971).

Stone technology remained important alongside bone. Ground and polished implements, pestles, querns and microlithic components indicate several chains of work: clearing or woodworking, processing plant foods, hunting and maintaining composite tools. The archaeological lesson is technological plurality. A 'Neolithic' community did not abandon small chipped stone simply because polished axes existed, nor did bone tools represent an inferior substitute for stone. Different raw materials were selected for different mechanical properties.

2.9 Plant economy at Chirand: what the seeds actually show

Palaeobotanical work at Chirand is unusually important for reconstructing subsistence. Vishnu-Mittre identified food-plant remains from Neolithic levels including rice, barley, lentil and field pea; later syntheses also discuss wheat and other pulses in the Bihar Neolithic record. These finds establish cultivation and consumption of multiple crops rather than a rice-only economy (Vishnu-Mittre 1972; Pokharia et al. 2017).

The chronology of the oldest Chirand plant remains has long been difficult because some early radiocarbon determinations were internally inconsistent. That problem should not be hidden by quoting one spectacular early number. Modern regional syntheses commonly place the Bihar Neolithic broadly in the late third to second millennium BCE, with Chirand often discussed around c. 2000–1500 BCE or somewhat wider depending on calibration and phase definition. The safe historical conclusion is the presence of a settled food-producing community in later prehistory, not an artificially precise founding year.

The combination of rice with winter cereals and pulses is socially more informative than a single crop label. It implies knowledge of different growing seasons and a household calendar that could distribute labour across the monsoon and cool seasons. Whether every listed crop was produced locally in every phase cannot be assumed; nevertheless, the assemblage supports a diversified plant economy.

2.10 Animals, hunting and aquatic resources at Chirand

The Neolithic economy was not a replacement of wild foods by domestic foods. Archaeozoological summaries from Chirand include domestic cattle, buffalo, sheep, goat and pig together with hunted deer, wild boar and other wild fauna. Fish, tortoise, molluscs and other aquatic resources fit the site's riverine setting. This is better described as a mixed agro-pastoral-foraging economy than as an agricultural economy with hunting as a marginal survival (Sinha 1994; eHRAF Ganges Neolithic synthesis).

The presence of wild fauna cannot by itself tell us the social organization of hunting, and cut-marked bones do not reveal whether particular species carried ritual meanings. Those questions require evidence not presently available. What can be said is that cultivation, animal keeping, fishing, hunting and gathering were compatible activities within one settlement system.

2.11 Chechar–Kutubpur: direct prehistoric evidence in modern Vaishali district

Chechar–Kutubpur is central to Volume II because it provides excavated prehistoric evidence inside present Vaishali district, close to the later landscape of Vaishali and Vajji. The Archaeological Survey of India's 1977–78 excavation report describes Period I as a pre-metal occupation over natural soil. Post-holes and burnt clay with reed impressions indicate wattle-and-daub houses plastered with husk-tempered earth; the available evidence suggested that at least some structures were circular. Most importantly for subsistence, the report characterized the economy as developed and rural, with agriculture accompanied by hunting and angling (Archaeological Survey of India 1977–78: 17–18).

The report's wording must be used carefully. 'Developed rural economy' is an excavator's interpretation, not a census of occupations. The direct evidence is architectural traces, tools, ceramics and subsistence indicators. The absence of metal in Period I helps distinguish the horizon technologically, but it does not by itself supply an absolute date. Nor does the site prove that the later city of Vaishali grew directly from this settlement without interruption. What it does prove is that food-producing communities occupied the Ganga-side alluvial zone of modern Vaishali before the urban and republican histories treated in later chapters.

2.12 Architecture and settlement permanence at Chechar–Kutubpur

Wattle-and-daub architecture is often archaeologically modest because walls decay and only post-holes, floors and burnt clay survive. At Chechar–Kutubpur, however, the combination of post-hole patterning, reed impressions and plastering material is enough to move interpretation beyond a transient camp. It indicates constructed domestic space and investment in maintaining a dwelling. The reported circular plan also places the site within a wider range of Neolithic house forms known from the Middle Ganga Plain.

Permanence should not be understood as immobility. Households could occupy a village for many years while members moved seasonally for fishing, grazing, hunting, fuel, raw materials or marriage exchange. Archaeology of a settlement mound records where durable activities accumulated, not the full annual movement of its inhabitants.

2.13 A subsistence mosaic, not a staircase of progress

The older language of 'food gathering' followed by 'food production' can imply a clean evolutionary threshold. The Bihar evidence is more usefully understood as a mosaic. Cultivated crops, domestic animals, wild game, fish and gathered plants coexisted. Different resources reduced different risks: cereal cultivation could generate storable calories; herds converted vegetation into meat and milk; fishing exploited predictable aquatic niches; hunting and gathering widened the seasonal food base.

This mixed system is exactly what should be expected in floodplain settings with strong seasonal contrasts. Households did not need to choose once and for all between farming and foraging. Their economic resilience may have depended on retaining several strategies. The proportion of each strategy almost certainly varied by site, year and season, and the surviving archaeological record does not permit a single percentage allocation.

Figure 6 — Prehistoric subsistence as a seasonal mosaic rather than a one-way transition from foraging to farming (colour analytical diagram).

2.14 Rice and the wider Middle Ganga problem

Rice occupies a special place in debates over the Neolithic of the Middle Ganga Plain, but the history of rice should not be made simpler than the archaeobotanical evidence allows. Sites such as Lahuradewa in eastern Uttar Pradesh have produced very early rice-related evidence and have transformed discussion of cultivation in the region. At the same time, scholars have debated whether the earliest rice remains represent fully domesticated rice, managed wild stands, cultivation before full domestication, or later intrusive material. Fuller and later archaeobotanical syntheses emphasize that domestication is a biological and cultural process whose chronology cannot be established from the mere presence of rice alone (Fuller 2006; Pokharia et al. 2017).

For Mithila–Vajji–Anga history, Lahuradewa is therefore comparative evidence, not local proof. It demonstrates that early cultivation and rice management in the wider Middle Ganga world may have deep roots. It does not prove that the same practices began at the same date in Vaishali, Saran, Bhagalpur or the Nepal Tarai. Local chronology must come from local contexts.

2.15 Crop diversity and seasonal scheduling

The combination of rice, barley, wheat and pulses documented in the wider Neolithic–early historic Ganga archaeobotanical record points toward increasingly complex seasonal scheduling. Rice generally belongs to the monsoon cycle, while barley and wheat are winter crops in the modern region. Pulses can occupy several niches in rotation or mixed cultivation. Even without assuming modern agronomy, the archaeological presence of crops with different ecological requirements indicates accumulated practical knowledge of soils, rainfall and season.

Such scheduling has social implications. Sowing, guarding, harvesting, threshing, processing and storage concentrate labour at particular times. Households must coordinate labour and cope with sickness, flood or crop failure. Yet archaeology rarely reveals the rules by which labour was allocated. It would be unjustified to assign particular tasks to men, women or named social groups simply because later ethnographies do so.

2.16 Domesticated animals and the limits of identification

Cattle and other domestic animals broadened the economic base of Neolithic communities. They supplied meat and potentially milk, dung, traction or transport, although each use requires independent evidence. A cattle bone identified as domestic does not prove plough agriculture. Likewise, sheep and goats indicate managed herds but do not reveal ownership arrangements. The responsible reconstruction separates species identification from the social uses that may or may not be archaeologically visible.

Faunal assemblages are also filtered by preservation and recovery technique. Small fish bones, bird bones and molluscs are easily undercounted in excavations that did not use fine sieving or flotation. Older excavation reports can therefore make terrestrial mammals appear disproportionately important. This is another reason to treat subsistence percentages with caution.

2.17 Wetlands, fish and floodplain knowledge

The riverine setting of Chirand and the reported angling at Chechar–Kutubpur underline a form of expertise that is easy to obscure in narratives centred on crops. Fishing requires knowledge of channel seasonality, spawning, shallow-water habitats and appropriate gear. Tortoise, molluscs and wetland plants extend the resource zone beyond the cultivated field. Oxbows, abandoned channels and marsh edges were productive environments even when they were inconvenient for permanent architecture.

This ecological knowledge also links Chapter 2 back to Chapter 1. Floods were not only disasters. Seasonal inundation renewed soils, created fisheries and rearranged grazing and gathering zones. The same process could also destroy houses or bury fields. Prehistoric settlement in an alluvial plain was therefore adaptation to variability, not conquest of a stable landscape.

2.18 Archaeological visibility: burial, erosion and false absences

The distribution map of known prehistoric sites is not a transparent map of where prehistoric people lived. A mound on a stable levee can accumulate visible deposits, while a low flood-basin camp can disappear beneath younger alluvium. A river cut may expose artefacts far from their original depositional context, and modern embankments, brick cutting, road building and agriculture can remove the upper part of a site. Survey intensity is uneven as well: some districts have received repeated archaeological attention, others very little.

For this reason, the absence of a reported Neolithic mound in a particular part of Mithila or Anga is not evidence that the area was empty. It is evidence that secure sites have not yet been demonstrated there. That distinction will be maintained throughout Volume II: archaeological silence is a research condition, not a licence to invent continuity.

Why “absence of sites” is not the same as “absence of people”

Floodplain archaeology is filtered by burial, erosion, channel migration and modern disturbance.

Figure 7 — Archaeological visibility on an active alluvial plain: burial, exposure and reworking can distort the apparent distribution of prehistoric settlement (colour schematic).

2.19 Mobility within sedentary life

Sedentism is best treated as a spectrum. Circular huts, floors and repeated occupation indicate residential investment, but a village-based household can still be highly mobile in its use of the landscape. Fishing trips, herd movements, hunting, raw-material procurement and visits to related communities create networks extending beyond the mound. The settlement is a node in those movements, not their boundary.

This perspective helps reconcile two kinds of evidence that are sometimes made artificially contradictory: durable domestic architecture and continued exploitation of wild resources. A household need not be a permanently enclosed farming unit to be sedentary in archaeological terms.

2.20 Material circulation without invented trade routes

Beads, stone raw materials, shell, ivory and other objects at Neolithic sites invite questions about circulation. Some materials may have been obtained locally; others may have moved through exchange or seasonal travel. Without geochemical sourcing, however, it is unsafe to draw precise trade routes. The presence of a bead made from a visually distinctive stone is not enough to identify a quarry, a merchant class or a long-distance market.

The correct historical inference is more modest: prehistoric households were connected to material landscapes wider than the immediate dwelling area, and some objects probably travelled between communities. Chapter 12 addresses trade only when stronger evidence for organized exchange becomes available.

2.21 What cannot yet be reconstructed: language, caste and political form

Nothing in the Patu, Chirand or Chechar–Kutubpur evidence permits identification of a spoken language. Archaeology does not allow these communities to be labelled Maithili-, Angika- or Bajjika-

speaking. Nor does it demonstrate the caste categories documented in much later periods. Burial practice, house size and artefact variation can sometimes indicate social differentiation, but the present evidence is insufficient to reconstruct a named hierarchy.

The same applies to political organization. A cluster of houses does not prove a chiefdom; the absence of a palace does not prove egalitarianism. The social scale of Neolithic communities can be explored through settlement size, storage, production and differential access to resources, but the present north-Bihar data are not rich enough to support a detailed constitutional model.

2.22 The Anga zone: a deliberate boundary of this chapter

For the eastern Bihar zone later associated with Anga, the archaeological sequence becomes substantially clearer in Chalcolithic and Black-and-Red-Ware horizons at sites such as Oriup and Champa. Excavations at Oriup, near Antichak in Bhagalpur district, identified a Chalcolithic Period I beneath later NBPW, Pala and medieval occupations. Champa likewise produced lower black-and-red-ware horizons below its early historic development. These are important, but they belong chronologically and analytically to Chapter 3.

This deliberate boundary prevents a common form of narrative inflation. Because Anga is historically prominent in the first millennium BCE, there is a temptation to supply it with an equally detailed Neolithic prehistory whether or not excavated evidence exists. Volume II will instead allow different regions to have different levels of prehistoric visibility.

2.23 Nepal–India comparison without a single origin story

Patu and the north-Bihar Neolithic sites belong to different archaeological traditions and ecological settings. Patu represents an early-Holocene lithic adaptation in the Siwalik foothills; Chirand and Chechar–Kutubpur represent later food-producing settlement in the Gangetic plain. Their inclusion in one chapter does not imply descent of one from the other. It demonstrates that the later trans-border region contained several prehistoric trajectories.

This plurality is historically valuable. The later cultural connectedness of Mithila across India and Nepal need not be justified by inventing a single prehistoric people. Long-term connectivity can emerge repeatedly through routes, marriage, markets, pilgrimage, language and political institutions in much later periods. Prehistory supplies a deep human landscape, not a charter of modern identity.

2.24 Conclusions: what Chapter 2 establishes

Four conclusions are secure enough to carry forward. First, prehistoric occupation is documented both in the eastern Nepal foothill zone and in the north-Bihar alluvial plain, but the archaeological traditions are not identical and should not be collapsed. Second, Neolithic communities at Chirand and Chechar–Kutubpur combined built domestic space with mixed subsistence: cultivation and animal keeping existed alongside hunting, fishing and gathering. Third, alluvial geomorphology strongly filters what survives and what is discovered, so archaeological absence must remain an open research question. Fourth, none of this evidence licenses the projection of later language, caste, political or regional identities into prehistory.

Chapter 3 begins where the material record becomes broader: Chalcolithic and early agrarian communities, increasing settlement numbers, copper alongside stone and bone, changing ceramic traditions, and clearer evidence in the eastern Bihar/Anga zone. The transition will be treated as a regional process with local differences, not as a universal stage that arrived everywhere at once.

Table 2.1 — Principal archaeological anchors and limits of inference

Site / zone	Secure signal	Subsistence / settlement	Main caution
Patu / Rato Khola, Mahottari	Contextualized cobble-tool industry on older terraces; early-Holocene dating framework	Human occupation and stone-working in a forested foothill/stream environment	Not evidence for farming or later Mithila/Madhesh identity
Chirand, Saran	Neolithic settlement with huts, stone and rich bone/antler industries, plant and animal remains	Mixed cultivation, animal keeping, hunting, fishing and gathering	Early dates are debated; do not force one exact founding date
Chechar–Kutubpur, Vaishali	Pre-metal Period I; post-holes, reed-impressed daub, circular huts; agricultural and hunting/angling evidence	Food-producing rural settlement in present Vaishali district	Small excavation; no direct line may be assumed to later Vaishali city or Vajji polity
Senuwar / Lahuradewa	Well-studied regional comparators for farming and archaeobotany	Help frame crop and chronology questions in the wider Middle Ganga region	Comparative evidence only; not local proof for Mithila/Vajji/Anga

CHAPTER 3 — CHALCOLITHIC AND EARLY AGRARIAN COMMUNITIES

3.1 Scope: an archaeological label, not a people

“Chalcolithic” is used here in its conventional archaeological sense for assemblages in which copper appears alongside stone, bone and other technologies. It does not name an ethnicity, language, polity or biological population. In the Middle Ganga Plain, copper is often scarce, while black-and-red ware, microlithic or ground-stone tools, bone implements, wattle-and-daub architecture and farming evidence continue from earlier contexts. For that reason the term is most useful as a descriptive chronological label, not as a claim that metal transformed every aspect of life at once.

3.2 Why Chapter 3 begins with continuity rather than a “revolution”

The excavated sequences do not support a simple staircase in which a Neolithic village abruptly becomes Chalcolithic after the arrival of copper. At Chirand, Chechar–Kutubpur and comparative sites farther south and west, older technologies persisted. House construction remained largely organic; microliths and bone tools continued; cultivation, fishing and animal use remained central. The significant change is therefore an enlargement and recombination of technological and economic repertoires rather than the instantaneous replacement of one system by another (Singh 2004; Archaeological Survey of India 1962–63, 1968–69).

3.3 Chronology is regional and must remain provisional

There is no single Chalcolithic date range that can be imposed on the whole Middle Ganga Plain. Site sequences begin and end at different times, radiocarbon programmes are uneven, and older excavations were often dated primarily by ceramic comparison. Recent reassessments of Early Farming and Chalcolithic chronologies in the Ganga Plain emphasize precisely this diversity. Senuwar, for example, provides a well-studied comparative sequence from Early Farming into a developed agrarian/Chalcolithic phase, but its dates cannot simply be copied onto north-Bihar or Bhagalpur sites (Singh 2004; Pokharia and colleagues in Indian Archaeology 1990–91; comparative discussion in recent radiocarbon reassessments).

3.4 Black-and-red ware: useful marker, dangerous identity label

Black-and-red ware (BRW) is a recurrent ceramic component in Chalcolithic and later horizons of the Middle Ganga Plain. Its surfaces reflect firing conditions that create dark and red zones on the same vessel. Archaeologists use its fabric, shape, finish, painted decoration and stratigraphic associations to compare assemblages. Yet BRW cannot be equated with one tribe, language or migration. Similar firing results and vessel traditions can occur across broad areas and long spans. In this volume pottery is therefore evidence for technology, food practice, chronology and interaction—not a shortcut to ethnic history.

3.5 Chirand: a long-lived riverine sequence

Chirand remains one of the essential regional anchors because repeated excavation exposed a deep sequence in which farming, fishing, hunting, bone working, microlithic traditions and pottery can be followed through time. Early reports described black-and-red ware, microliths, ivory and bone objects together with a few copper pieces in the pre-NBPW horizon; later work added structural evidence including post-holes, hearths, burnt-earth floors and reed or bamboo impressions in clay. The assemblage shows

technological addition rather than abandonment: copper occurs, but bone and stone remain economically important (Archaeological Survey of India 1962–63; 1968–69; Verma 2007).

3.6 Domestic architecture at Chirand

The architecture associated with these levels was largely perishable. Mud plaster, reed or bamboo impressions, post-holes and burnt floors indicate houses whose superstructures would leave only fragmentary archaeological traces. Hearths and ash pits show repeated domestic activity. Such evidence is especially important for social history because it directs attention away from elite monuments toward ordinary residential investment, fuel use, food preparation and household maintenance. It also warns against assuming that the absence of masonry means an absence of stable settlement.

3.7 Chechar–Kutubpur: a Vaishali-district agrarian anchor

The 1977–78 Archaeological Survey of India excavation at Chechar–Kutubpur, on the northern bank of the Ganga in present Vaishali district, described the earliest occupation as a developed rural economy in which agriculture, hunting and angling all mattered. Post-holes and clay chunks bearing reed impressions indicated wattle-and-daub houses plastered with husk-mixed earth. The excavators did not recover metal from the earliest phase in that season, a useful reminder that a community participating in a broader Chalcolithic ceramic horizon need not possess abundant copper (Archaeological Survey of India 1977–78: 17–18).

3.8 Chechar revisited: black-and-red ware, bone and copper

A later ASI excavation at Chechar in 1988–89 documented black-and-red ware in coarse and fine varieties, red-slipped ware and burnished black-and-red ware in Period I, together with bone tools, arrowheads, points and copper pieces. The difference between the two excavation reports should not be forced into contradiction: they sampled different areas and phases of a large, eroding mound. Taken together, they show both the uneven archaeological visibility of small metal objects and the persistence of bone technology within the same broad cultural horizon (Archaeological Survey of India 1988–89).

Evidence matrix: selected Chalcolithic / early agrarian anchors

	Black-and-red ware	Copper objects	Bone/lithic tools	Domestic structures	Agrarian evidence	Aquatic resources
Chirand (Saran)	strong	strong	strong	strong	strong	strong
Chechar (Vaishali)	strong	reported	strong	strong	reported	strong
Panda (Samastipur)	strong	strong	strong	reported	strong	—
Oriup (Bhagalpur)	strong	strong	strong	strong	—	—
Senuwar (comparator)	strong	strong	strong	strong	strong	reported

Senuwar is used as a Middle Ganga comparator, not as evidence for Mithila, Vajji or Anga.

Figure 8 — Evidence matrix for selected Chalcolithic and early agrarian anchors. “Strong” indicates direct or repeatedly reported evidence in the cited excavation literature; “reported” indicates more limited evidence. Senuwar is included only as a Middle Ganga comparator.

3.9 Panda in Samastipur: direct evidence within the Mithila plain

Panda (often written Pāṇḍ/Pand in excavation literature) is especially important because it lies in present Samastipur district, well inside the modern Mithila plain. Excavation assigned Period I to a Chalcolithic phase characterized by black-and-red ware, black-slipped, red and grey wares. Reported finds included stone hammers, axes and pestles, a copper hook, bone arrowheads, micro-beads and an earthen oven containing husk. This combination ties ceramic technology directly to domestic production and plant processing rather than to an abstract “culture” label (Choudhary 2005; Indian Archaeology 2001–02 and 2002–03).

3.10 The oven and husk at Panda: small evidence, large implications

An oven mixed with husk is a modest find, but its evidentiary value is high. Husk may enter clay intentionally as temper or accidentally through processing debris; either way it places cereal-processing waste within the domestic activity zone. It does not by itself identify the cereal species or prove specialized craft production. What it securely supports is an agrarian household environment in which plant residues, heating installations and ceramic vessels were entangled in everyday work.

3.11 Oriup: the clearest Chalcolithic anchor in the Anga/Bhagalpur zone

For the eastern zone later associated with Anga, Oriup in Bhagalpur district is a crucial stratified site. Trial excavation in 1966–67 revealed a Period I with black-and-red ware, an oven, a circular fireplace, a copper bangle, an archaic terracotta figurine and a microlithic core. The report also noted erosion probably connected with a river formerly flowing close to the site. Oriup therefore provides what Chapter 2 deliberately withheld: secure Chalcolithic occupation in the Bhagalpur zone without requiring an invented Neolithic ancestry for historical Anga (Archaeological Survey of India 1966–67).

3.12 Oriup and the river: settlement history includes erosion history

The excavators’ observation that part of Oriup had been eroded is methodologically important. A river can remove early occupation, bury it under silt or preserve only discontinuous pockets. Apparent cultural “gaps” may therefore reflect geomorphology as well as human abandonment. The same caution applies across the Ganga, Gandak, Ghaghara and Kosi-influenced plains. Settlement maps must be read as maps of surviving and discovered deposits, not as complete maps of ancient population.

3.13 Champa: separating the later city from the earlier regional horizon

Champa is indispensable to the later history of Anga, but its urban prominence should not be projected backward automatically. Excavations of the fortified settlement concentrated on NBPW and later structural phases; black-and-red ware occurred in association with some early rampart deposits, but the published sequence is not as straightforward a Chalcolithic anchor as Oriup. This volume therefore treats Oriup as the firmer source for a Chalcolithic Bhagalpur horizon and reserves Champa’s securely documented urban development for later chapters (Indian Archaeology 1970–71, 1971–72, 1972–73; Archaeological Survey of India, Indian Archaeology Today).

3.14 Copper was valuable because it was limited

The rarity of copper objects at many Middle Ganga sites is itself historically informative. Metal had to be acquired from geological zones outside most alluvial settlements, whether through direct movement, exchange or down-the-line transfer. Small bangles, hooks, wires, points or fragments therefore need not indicate a “copper economy.” They show selective access to a material with properties different from stone, bone or wood. The social value of copper may have exceeded its numerical share in the toolkit, but status cannot be inferred without contextual evidence.

3.15 Stone and bone did not become obsolete

Microlithic cores and flakes, ground stone tools, bone points, pins and arrowheads continue in contexts that also contain copper. This continuity is rational rather than technologically “backward.” Stone is durable and can be resharpened; bone is light and easily shaped; organic handles and shafts multiply the possible uses of both. A household choosing among materials was solving specific tasks, not moving through a textbook hierarchy from stone to copper to iron.

Composite technology rather than a copper revolution

“Chalcolithic” does not mean copper replaced older technologies; the archaeological record shows a composite toolkit.

Figure 9 — Composite technology rather than a copper revolution: stone, bone, copper, ceramics and organic materials remained complementary.

3.16 Agriculture: continuity, diversification and evidence control

Chapter 2 established that rice and a wider cereal–pulse package were already present in parts of the Bihar early-farming record. Chalcolithic communities inherited and elaborated those practices. Direct botanical evidence is strongest at sites with systematic recovery programmes; elsewhere, husk impressions, grinding tools, storage facilities and settlement context provide indirect support. The correct inference is therefore graded by site: rich archaeobotanical reconstruction where plant remains exist, and more limited agrarian interpretation where only processing equipment or husk-tempered clay survives.

3.17 Senuwar as a comparator for crop scheduling, not a substitute for Mithila evidence

Senuwar in the Kaimur region lies outside the Mithila–Vajji–Anga core, but its excavated Early Farming–Chalcolithic sequence is useful for understanding what a diversified agrarian economy can look like when plant remains are well preserved and studied. Archaeobotanical reports include rice, barley, wheat, millets and several pulses across the sequence. The site demonstrates the potential complexity of second-millennium BCE farming in the wider Middle Ganga world; it does not prove that Panda, Chechar or Oriup cultivated exactly the same crop package (Singh 2004; Indian Archaeology 1990–91).

3.18 Animals, fish and the persistence of broad-spectrum subsistence

Agriculture did not eliminate hunting, herding or fishing. Chechar’s excavation report explicitly mentioned angling; Chirand preserves abundant aquatic and animal evidence; comparative sites show cattle and other domesticates alongside wild fauna. The economic logic of riverine plains encouraged such diversity. Crop failure, flood timing and seasonal labour could be buffered by fisheries, grazing, hunting and gathered resources. “Agrarian” therefore means agriculture became structurally important, not that every household lived by crops alone.

Seasonal coordination in an early agrarian riverine household

Figure 10 — Seasonal coordination in an early agrarian riverine household. The diagram is analytical rather than a reconstruction of one excavated household.

3.19 Hearths, ovens and the archaeology of daily work

Hearths at Chirand and Oriup and the oven reported at Panda bring the analysis to the scale of repeated daily labour. Fire transformed food, hardened clay, provided warmth, processed plant and animal materials and may have supported small crafts. Yet the same installation can perform several tasks across its life. Archaeology usually recovers the installation and residues, not a written label describing its function. Interpretation should therefore remain contextual and probabilistic.

3.20 Pottery and the social organisation of food

The expansion of ceramic repertoires—bowls, dishes, jars, basins, dish-on-stand forms and other vessels—made possible different combinations of cooking, serving, storage and transport. Variation in fabric and finish may reflect intended use, skill, firing control and local taste. It does not automatically prove full-time potter castes or centralized workshops. Repetition and standardisation can indicate specialized knowledge, but the labour organisation behind production remains a separate question.

3.21 Beads and material circulation

Stone, terracotta and other beads reported from several sites show that households invested labour in personal adornment and small portable objects. When raw materials are non-local, beads can also register circulation between ecological zones. Nevertheless, a bead is not a trade route. Without sourcing studies, quantities, workshop debris or distributional patterns, the safest conclusion is that Chalcolithic communities participated in material networks wider than a single settlement, while the precise mechanism—gift, exchange, itinerant craft or household travel—remains open.

3.22 Settlement growth without invented population totals

Regional syntheses observe that Chalcolithic sites are more numerous than securely identified earlier farming sites in many parts of the Middle Ganga Plain. This may reflect population growth, longer-lived settlements, increased ceramic visibility, greater archaeological attention, or all four. It is reasonable to speak of expanding and more archaeologically visible agrarian settlement; it is not reasonable to convert site counts directly into ancient population numbers without systematic survey areas and correction for preservation bias.

3.23 Household labour and gender: what archaeology cannot assign safely

Grinding grain, tending animals, fishing, making pottery, repairing houses and managing fires all required recurrent labour. Archaeology can reconstruct those tasks far more securely than it can assign them to men, women or fixed age groups. Later ethnographic patterns cannot simply be projected backward several millennia. Gendered labour undoubtedly existed, but its exact divisions must remain unknown unless burials, use-wear, spatial patterning or other context supplies stronger evidence.

3.24 Social differentiation: inequality is possible, hierarchy is not yet demonstrated

Differences in access to copper, beads or particular vessel types may have carried social meaning, but the sites discussed here do not yet justify a detailed hierarchy of chiefs, castes or classes. Houses are incompletely exposed; burials are limited; storage capacities are rarely quantified; and prestige goods are few. The responsible position is therefore intermediate: these communities were socially organised and probably

differentiated in multiple ways, but the form and permanence of inequality cannot be reconstructed with confidence.

3.25 Rivers, fields and the agrarian landscape

The most durable economic transformation was not copper itself but the deepening relationship between households and managed landscapes. Fields, grazing areas, fishing places, fuel zones, clay sources and routes had to be revisited season after season. Floodplain agriculture demanded knowledge of water timing and soil moisture; river migration could reward one location and destroy another. Early agrarian history is therefore also environmental history—a continuous negotiation among cultivation, mobility and unstable alluvial terrain.

3.26 From Chalcolithic to iron-using and NBPW horizons

Iron and Northern Black Polished Ware appear at different dates and with different local sequences across the Middle Ganga Plain. At some sites iron enters while black-and-red ware and older tool traditions continue. The transition is therefore best represented as overlap. This matters for the next chapters: early historic urbanisation did not begin on an empty landscape. It drew upon already settled agrarian communities, river knowledge, craft traditions and exchange networks while reorganising them at new scales.

From early farming to early historic society: continuity, overlap and uneven change

Continuities: rice and other crops • cattle and fishing • wattle-and-daub houses • stone/bone tools • local ceramic traditions

Change is cumulative and regionally uneven—not a single “revolution” or a migration identifiable from pottery alone.

Figure 11 — From early farming to early historic society: continuity, overlap and uneven change rather than a universal technological break.

3.27 What this chapter establishes—and what it refuses to claim

Four conclusions can be carried forward. First, Chalcolithic communities are securely documented in the Vaishali, Samastipur and Bhagalpur zones through Chechar, Panda and Oriup, while Chirand provides a closely related north-Bihar riverine sequence. Second, agriculture, fishing, hunting and animal management remained complementary. Third, copper enlarged rather than replaced older technologies. Fourth, settlement and material circulation became more archaeologically visible before the early historic urban horizon. None of this identifies the inhabitants as “Maithil,” “Vajjian” or “Anga” peoples in a later linguistic or political sense. Those identities belong to later evidence and must be demonstrated there.

Table 3.1 — Selected Chalcolithic / early agrarian sites used in Chapter 3

Site / area	Core evidence used here	Agrarian / domestic indicators	Metal evidence	Interpretive limit
Chirand, Saran	BRW, microliths, bone/ivory, hearths, post-holes	Plant economy from earlier sequence; fish/animal remains; houses	Few copper pieces / objects	Long sequence; phase dates and labels revised across campaigns
Chechar–Kutubpur / Chechar, Vaishali	BRW, bone tools, post-holes, reed-impressed clay	Agriculture, hunting and angling explicitly reported	None in 1977–78 sample; copper pieces in 1988–89 Period I	Different trenches/phases should not be collapsed
Panda, Samastipur	BRW, black-slipped/red/grey ware, bone arrowheads, stone tools	Oven with husk; domestic equipment	Copper hook	Detailed botanical species not established by the oven alone
Oriup, Bhagalpur	BRW, oven, circular fireplace, microlithic core	Domestic fire installations; river-edge settlement	Copper bangle	Agrarian crop package not directly established in cited report
Senuwar, Rohtas (comparator)	Early Farming–Chalcolithic sequence, ceramics and tools	Rich multi-crop archaeobotanical record	Copper objects in Chalcolithic phase	Comparator outside Mithila–Vajji–Anga core; cannot substitute for local evidence

CHAPTER 4 — ARCHAEOLOGY OF FOOD AND EVERYDAY LIFE

4.1 Scope: food archaeology is not a prehistoric cookbook

This chapter asks what people cultivated, collected, herded, caught, processed, cooked, stored and discarded in the early agrarian landscapes introduced in Chapters 2 and 3. The archaeological record can answer parts of those questions, but it cannot recover a menu in the modern sense. Carbonised grains identify plants that entered fires or deposits; bones and shells identify animals present in the archaeological assemblage; querns, hearths and vessels reveal processing possibilities. None of these, by itself, establishes the proportion of a food in the diet, a named recipe, a ritual rule, or the social identity of the person who prepared it. The method therefore moves from direct residue to bounded inference. This is particularly important for Mithila, Vajji and Anga, because later textual cuisines and modern regional food identities are rich enough to tempt retrospective projection. They belong to later chapters and must not be used to fill prehistoric silence.

4.2 The preservation problem: most food disappears

Food is among the least evenly preserved categories of material culture. Leaves, milk, oils, soft fruits, cooked gruels and many roots normally leave little macroscopic trace unless they are charred, mineralised, waterlogged or preserved as microremains. Bone survival varies with soil chemistry and burning; fish bones can be lost through coarse excavation screens; tiny seeds may remain invisible unless flotation or fine sieving is used. The result is a strong preservation bias toward durable shells, bones and accidentally charred plant parts. The absence of a species from an excavation report may therefore mean that it was not present, that it decayed, that the relevant area of the settlement was not excavated, or that recovery methods did not capture it. Archaeobotanical and zooarchaeological evidence are strongest when sampling procedures, stratigraphy and identification criteria are published. Figure 15 formalises this filtering problem and is a standing caution for every quantitative-looking food list in this chapter.

Figure 12 — The preservation filter: archaeological food remains are a selective sample

Figure 12 — The preservation filter: archaeological food remains are a selective sample. Absence from the recovered assemblage is not automatically absence from diet.

4.3 Chirand: the strongest local conjunction of plant and animal evidence

Chirand is unusually valuable because plant remains, animal bones, aquatic fauna, tools, pottery and domestic features can be considered within the same long archaeological sequence. Vishnu-Mittre's study of the Neolithic plant economy reported rice, barley, lentil and field pea from the lower levels, while later summaries also record wheat and pulses such as mung. Nath and Biswas identified a faunal assemblage including humped cattle, buffalo, sheep, pig, dog, deer, elephant, rhinoceros, carp and turtles. Excavation reports add hearths, ovens, bone tools and large ceramic assemblages. Taken together, these materials show a food-producing economy that was neither narrowly cereal-based nor simply a continuation of mobile hunting. Cultivation, animal husbandry, hunting, fishing and the use of wetland resources were concurrent. The evidence is nevertheless an assemblage of different recovery histories; it should not be converted into percentages of diet unless a specific quantified study supports such calculation (Vishnu-Mittre 1972; Nath and Biswas 1980; Verma 2007).

4.4 Rice was central, but 'rice economy' should not erase crop diversity

Rice is the most persistent crop in discussions of the Middle Ganga Neolithic because the ecology of the plain favoured wild and cultivated *Oryza* and because rice has a long later cultural importance. At Chirand, however, the archaeobotanical record also includes barley, lentil and field pea, with wheat and other pulses reported in the wider excavation literature. Senuwar, used here as a comparator rather than as a substitute for evidence from Mithila or Anga, shows even more clearly how rice could coexist with winter cereals, pulses and millets. This diversification matters economically. A household cultivating crops with different sowing and harvesting seasons could spread labour demands and reduce the danger of dependence on a single harvest. It also complicates simple stories in which rice agriculture alone explains sedentism. The archaeological record instead points toward combinations of crops adapted to monsoon, winter and local moisture regimes (ASI 1986-87; ASI 1990-91; Saraswat 2004).

4.5 Cultivation is not the same thing as domestication

The distinction between cultivation and biological domestication is essential when discussing early rice. Cultivation refers to human practices such as sowing, tending, water management and harvesting; domestication refers to inherited biological changes in the plant population. Archaeobotanical debates over shattering, rachis morphology and grain form show that these processes need not coincide. Lahuradewa, outside the core study region but within the wider Middle Ganga environmental zone, has been central to debate over very early rice use and cultivation. Later reassessments emphasise that the emergence of fully domesticated rice was protracted. For this volume, Lahuradewa is therefore comparative evidence for the antiquity and complexity of human-rice relationships, not proof that the same chronology applies to every site in Mithila, Vajji or Anga. At Chirand and Senuwar, the safer historical claim is that rice cultivation formed part of established village food economies by their excavated Neolithic phases (Fuller 2011; Tewari et al. 2008).

4.6 Winter crops altered the annual labour calendar

Barley, wheat, lentil, field pea and grass pea are not merely additions to a species list. When securely associated with winter cultivation, they imply a second agricultural season alongside monsoon cropping. The Senuwar palaeobotanical reports are particularly informative: Period IA included rice, barley, dwarf wheat, sorghum and ragi millets, lentil, grass pea and field pea, with weeds associated with cultivated fields. The coexistence of monsoon and winter crops implies repeated cycles of land preparation, sowing, weeding,

harvesting, threshing, drying and storage across much of the year. Such scheduling can support more stable sedentary households, but it also increases the need for labour coordination and the management of seed reserves. Because Senuwar lies in the Kaimur zone, this evidence is used as a regional model of what diversified farming could involve, while Chirand's local crop list provides the firmer anchor north of the Ganga (ASI 1990-91).

4.7 Field weeds are historical evidence too

Archaeobotanical reports sometimes list weeds beside crops, and those minor taxa are easy to overlook. Yet weeds can indicate the disturbed soils and seasonal fields in which crops grew, harvesting height, crop cleaning and the movement of seed contaminants. At Senuwar, taxa such as *Vicia*, *Setaria*, *Rumex* and wild rice occur with food grains. They remind us that a cultivated field was not a modern monoculture but an ecological community. Some weeds may have been tolerated, gathered, grazed by animals or accidentally brought into the settlement with harvested crops. Their presence also cautions against treating every recovered seed as a deliberately cultivated food. Archaeobotanical interpretation therefore depends on assemblage context rather than a binary division between 'crop' and 'wild plant' (ASI 1990-91; Saraswat 2004).

4.8 From harvest to meal: processing created the archaeological signature

A cereal does not move directly from field to pot. Harvesting can leave straw and husk; threshing separates grain; winnowing and cleaning remove chaff and weeds; pounding or grinding changes grain size and texture; soaking, parching, boiling or roasting changes the probability that food survives archaeologically. Querns, mullers, pestles and grinding stones therefore belong to the history of food just as much as charred grain. The food economy was partly an economy of repetitive processing labour. The archaeological challenge is that a quern can grind more than one substance and a pestle can serve multiple tasks. Consequently, the presence of grinding equipment supports intensive plant processing but does not identify a specific dish. Figure 12 sets out this evidence chain from residue and tool to appropriately limited historical claim.

Figure 13 — From archaeological residue to a defensible history of food. Different evidence classes support different levels of inference.

4.9 Husk in clay: by-product, temper and household waste

The earthen oven mixed with husk excavated at Panda in Samastipur is a small but unusually concrete piece of evidence for the proximity of food processing and domestic construction. Husk can be incorporated into clay intentionally as temper, swept into building material as processing waste, or burned as fuel. Each pathway begins with the same underlying fact: cereal by-products circulated through the household rather than disappearing at harvest. Similar husk impressions in burnt clay and pottery at other Middle Ganga sites show how food production entered architecture and craft. Panda therefore provides a direct Mithila-plain anchor for the integration of crop processing, fuel, construction and cooking technology, even though the find does not by itself identify the cereal species used in the oven fabric (Choudhary 2005; ASI 2001-02; ASI 2002-03).

4.10 Cattle were more than meat

Nath and Biswas found humped cattle to be the most prominent domestic animal in the Chirand faunal collection, with buffalo, sheep and pig also represented. A food history must resist reducing these animals to carcasses. Cattle and buffalo could contribute traction, manure, mobility, hides and—where dairying occurred—milk, although direct evidence for each use must be demonstrated independently. Bone assemblages can show slaughter and species representation more securely than they can establish secondary products. The historical importance of herding lies partly in its complementarity with cultivation: animals could graze fallow or marginal land, consume crop residues and produce manure, while households retained a movable store of value and food. This mixed agro-pastoral logic is better supported than a specialised pastoral or specialised arable economy for Chirand (Nath and Biswas 1980).

4.11 Sheep, goats and pigs diversified household risk

Smaller livestock occupy different ecological and labour niches from cattle. Sheep and goats can exploit browse and grazing that would not support field crops, while pigs can convert household refuse and wetland-edge resources into animal biomass. Their bones at early farming sites therefore indicate a broader strategy of resource use. At Chirand, sheep and pig were well represented in the analysed assemblage; goat is also reported in archaeological syntheses of the site. The precise balance among these taxa remains dependent on identification and sample size, but their presence demonstrates that domestic animal management was not restricted to cattle. Mixed herds and pigs could buffer harvest failure, although this chapter avoids estimating meat availability or herd size without age profiles and quantified faunal data (Nath and Biswas 1980; Verma 2007).

4.12 Hunting remained economically rational

Wild deer, rhinoceros and elephant in the Chirand faunal record show that domestication did not eliminate engagement with uncultivated landscapes. Deer are especially important because they supplied meat and antler; antler and long bones could be transformed into points, awls and other implements. The presence of large wild mammals also speaks indirectly to habitats that no longer survive in the same form around the site. Hunting may have protected fields, supplied food, provided raw material or had social meanings that the bones alone cannot recover. What can be said securely is that early farmers did not draw a hard economic boundary between 'agriculture' and 'foraging'. Their subsistence system remained broad-spectrum and ecologically opportunistic (Nath and Biswas 1980).

4.13 Fish, turtles and molluscs place wetlands inside the economy

Aquatic remains are among the most important correctives to land-centred histories of early farming. Chirand yielded fish, turtles and shell; Oriup in Bhagalpur produced bone fishing hooks, possible net-related terracotta pieces and utilised tortoise shell; broader Ganges Neolithic syntheses also emphasise fish, molluscs and turtles. These finds show that rivers, oxbows, ponds and floodplain depressions were food-producing spaces in their own right. Fishing could be intensified seasonally as water receded and fish became concentrated, while monsoon expansion created different habitats and transport conditions. The evidence does not show that every settlement used the same techniques, but it makes clear that an agrarian village in this landscape was not economically confined to its fields (ASI 1966-67; Nath and Biswas 1980).

Figure 14 — A riverine foodscape: fields, herds, wetlands, forest edge and river routes fed into household processing and consumption.

4.14 Oriup: fishing technology in the Anga/Bhagalpur zone

Oriup provides the strongest excavated food-related evidence used here for the eastern zone later associated with Anga. In Period I, the excavators recorded an oven, a circular fireplace, numerous bone fishing hooks, bone points, terracotta objects interpreted as possibly associated with fishing nets, and pieces of tortoise shell used as tools. The settlement stood close enough to a river channel for erosion and silt deposition to affect its stratigraphy. Food procurement, cooking and river geomorphology can therefore be read together at the site. This is a more defensible early history of the Anga landscape than projecting the later commercial or literary identity of Champa backwards into the Chalcolithic horizon (ASI 1966-67).

4.15 Wild plants and forest-edge foods are structurally undercounted

Wild fruits, leafy plants, tubers, mushrooms, honey and other gathered foods are much less visible than cereal grains, especially in ordinary oxidised alluvial deposits. Archaeobotanical records from the Middle Ganga region nevertheless include wild jujube and other taxa, while the ecology reconstructed from faunal remains implies woodland, grassland and wetland edges accessible to settlements. It is therefore reasonable to include gathering as one component of the food economy, but not to invent a detailed species list for sites that have not produced one. Forest and scrub zones also supplied fuel, timber, fibres and fodder. These non-food resources mattered to diet indirectly because cooking, storage, house construction and animal keeping all depended on them.

4.16 Fuel was part of food technology

Every cooked meal required energy, yet fuel is rarely treated as part of economic history. Wood charcoal, burnt clay, ash and hearths show repeated combustion, but identifying the exact fuel species requires anthracological study. Households could draw on wood, brush, dung, crop straw and husk in different combinations. The choice would affect labour, smoke, cooking temperature and pressure on surrounding vegetation. Panda's husk-tempered oven and the repeated hearths or ovens at Chirand and Oriup demonstrate that crop by-products and local biomass were integrated into domestic technology. Without direct fuel analysis, however, dung or particular wood species should remain possibilities rather than claims.

4.17 Hearths and ovens: repeated fire creates social space

At Chirand, hearths and oblong ovens were associated with domestic structures; Oriup Period I contained an oven and circular fireplace; Panda yielded an earthen oven. These installations mark places where heat was repeatedly controlled. They could be used for cooking, roasting, parching, boiling with vessels, heating water or craft processes, and a single installation may have served several functions through time. Earlier interpretations sometimes called larger or multiple ovens evidence of 'community cooking'. That is possible, but size alone does not prove communal consumption. The more secure inference is that food preparation was spatially organised inside or beside houses and that fire installations were maintained features rather than accidental burns (Verma 2007; ASI 1966-67; Choudhary 2005).

4.18 Pottery multiplied ways of transforming food

The spread of pottery changed the technical possibilities of food preparation even when exact recipes remain unknown. Bowls, jars, basins, dishes and other vessel forms could support boiling, soaking, serving, fermenting, carrying or storage. Sooting, residues, abrasion and use-wear can sometimes narrow these possibilities, but vessel shape by itself is not a recipe. At Chirand and the Chalcolithic sites discussed in Chapter 3, pottery repertoires become more varied and increasingly wheel-made in later phases. This diversification suggests growing differentiation among containment, cooking and serving tasks. It also created new surfaces on which food could be preserved archaeologically as carbonised crusts or absorbed residues, although systematic residue analysis remains limited for the regional sequence used in this volume.

4.19 Boiling, roasting and gruel are possibilities, not named dishes

A combination of cereals, pulses, pottery and hearths makes several cooking methods technologically possible. Grain may be boiled whole, cracked, ground into meal, parched or incorporated into mixed preparations; meat and fish may be roasted, boiled or dried. Archaeology can identify the equipment and ingredients more readily than the final culinary form. For this reason the chapter does not translate the assemblage into modern terms such as khichdi, roti, rice-beer or regional fish dishes unless later period-specific evidence independently supports them. Similarity between an ancient technical possibility and a later cuisine is not evidence of continuity. The archaeological contribution is to define the range of feasible transformations and the labour invested in them.

4.20 Storage: one of the hardest parts of the food cycle to measure

Storage is economically crucial because it turns a seasonal harvest into year-round food and seed, yet storage facilities are inconsistently preserved and identified. Large jars, pits, bins and raised containers can all store grain, but the same features can have other uses. Regional Neolithic and Chalcolithic sites provide comparative evidence for pits and storage vessels, while the Chirand record is clearer for pottery and domestic

structures than for a single, well-quantified storage system. It would therefore be unsafe to estimate surplus from the number of jars. The strongest inference is functional: diversified cropping and sedentary households require some means of holding seed and food between harvests, but the scale, ownership and duration of storage must be established site by site.

4.21 Food security came from diversity rather than guaranteed surplus

A household combining rice, winter crops, livestock, fish and gathered resources had several ways to respond when one source failed. Flood damage to a field might coincide with productive fishing; a poor rice harvest could make pulses, livestock or stored grain more important; seasonal wild foods could bridge lean periods. This ecological diversity is a plausible form of risk buffering, not evidence that famine was absent. Early farmers remained exposed to flood, drought, pests, animal disease and storage loss. Figure 14 therefore presents a seasonal scheduling model rather than a prosperity narrative. The historical point is that food security depended on coordinating resources with different seasonal rhythms.

Figure 15 — Seasonal scheduling and risk buffering in an early agrarian food system

Figure 15 — Seasonal scheduling and risk buffering in an early agrarian food system. Timings are schematic and varied locally.

4.22 Food waste is evidence of labour and choice

Ash lenses, charred seeds, broken vessels, cut or burnt bones and shell concentrations are often classified as refuse, but refuse is the endpoint of economic decisions. A charred grain may represent accidental burning during drying, a cooking loss or discarded spoiled food; a butchered bone records carcass processing; broken pots mark repeated replacement of household equipment. Middens and floor sweepings can also reveal where tasks took place. The challenge is that deposits may be redeposited by flooding, trampling, pits or later construction. Context is therefore as important as the object. The archaeology of food is strongest when it reconstructs sequences of action—acquisition, processing, cooking, consumption and discard—rather than simply listing species.

4.23 Household labour can be reconstructed more safely than gendered labour

Grinding grain, carrying water, tending animals, fishing, collecting fuel, cleaning crops, maintaining hearths and making or repairing containers all required recurring labour. These activities can be inferred from tools and installations, but assigning each task to women, men, children or particular status groups requires independent evidence. Later ethnography cannot be projected mechanically into the third or second millennium BCE. Archaeology may eventually use skeletal stress, activity markers, spatial patterning or burial

evidence to refine labour histories, but the sites discussed here do not justify a fixed gender division of food work. The most defensible conclusion is that household subsistence was labour-intensive and coordinated across several activities.

4.24 Feasting and inequality: attractive hypotheses need stronger proof

Large hearths, decorated vessels or concentrations of animal bone can invite interpretations of feasting and social competition. Such practices are well documented in many archaeological societies, but they must be demonstrated through context: unusually large serving sets, patterned deposits, high-value foods, repeated event layers or spatial segregation. The evidence reviewed for Chirand, Panda, Chechar and Oriup does not yet support a detailed hierarchy of elite and common diets. Differences in access are possible, especially as settlement complexity increases, but this chapter keeps them as research questions rather than narrative facts. The social archaeology of food begins with variation in deposits; it should not assume stratification before that variation is securely shown.

4.25 Floodplain food systems were mobile even when villages were sedentary

Sedentary settlement did not mean that the productive landscape was fixed. River channels migrated, low-lying areas flooded, oxbows formed and silt renewed or buried fields. People could shift cultivation plots, move livestock seasonally, fish at different water levels and collect resources from changing wetland margins. The erosion observed at Oriup and the geomorphological problems discussed in Chapter 1 show why archaeological sites preserve only fragments of these wider catchments. A village mound is therefore the residential node of a larger and mobile foodscape. Figure 13 represents this relationship among fields, herds, wetlands, forest edge and river routes.

4.26 Nepal and the northern Tarai: a boundary of evidence, not a blank history

The title of this volume includes India and Nepal, but the prehistoric and early agrarian food record is not equally documented on both sides of the modern border. The Patu evidence discussed in Chapter 2 concerns lithic occupation in the eastern Nepal Siwalik/foothill environment and does not provide an archaeobotanical food assemblage comparable to Chirand or Senuwar. It would be methodologically wrong to transfer the Bihar crop and livestock package northward merely because later Mithila spans the international boundary. For the Nepal Tarai, Chapter 4 therefore records an evidence gap. Later chapters, when textual, archaeological and historical documentation becomes stronger, will reconstruct Nepal-side agrarian and food histories on their own evidence.

4.27 The eastern Anga zone: direct fishing evidence, limited plant evidence

For the Bhagalpur/Oriup zone, Period I provides unusually vivid fishing and hearth evidence but not the same published archaeobotanical resolution available for Chirand or Senuwar. This asymmetry should shape the narrative. It is possible to say that riverine resources, tortoise shell, fishing hooks and controlled fire were part of everyday life at Oriup. It is not equally secure to reproduce the full Chirand crop list as though excavated at Oriup. Regional comparison can suggest questions—whether rice, pulses or winter cereals were grown—but those questions remain open until local plant remains are securely reported. This is how a cumulative history avoids turning geographic proximity into fabricated evidence.

4.28 Conclusion: an agrarian economy remained a mixed food economy

The archaeology of food changes the scale of early history. Instead of treating the Neolithic and Chalcolithic mainly as ceramic or technological labels, it reveals daily systems of cultivation, herding, fishing, hunting, processing, cooking and storage. Chirand anchors a diversified local food economy; Panda connects cereal by-products with domestic technology in the Mithila plain; Oriup places fishing and hearths firmly inside the early Anga/Bhagalpur landscape; Senuwar demonstrates, comparatively, the potential complexity of mixed seasonal agriculture. None of these sites justifies a reconstructed cuisine in the modern cultural sense. What they establish is more fundamental: early agrarian communities survived by coordinating multiple ecological zones, multiple species and repeated household labour. Chapter 5 moves outward from these food practices to the larger question of environment, mobility and settlement.

Table 4.1 — Food evidence and limits of inference

Evidence	Principal anchor	Strongest supported inference	Do not infer automatically
Charred grain / husk	Chirand; Panda; Senuwar (comparator)	Plant presence, crop processing; sometimes cultivation	Dietary percentage, named dish, ownership
Animal bone	Chirand	Species present; husbandry/hunting when context allows	Exact meat consumption, dairy or traction without evidence
Fish / turtle / shell	Chirand; Oriup	Aquatic-resource use and fishing technology	Year-round intensity or social status of fishers
Hearth / oven / ash	Chirand; Panda; Oriup	Repeated controlled heating	Specific recipe or communal feast
Querns / mullers / pestles	Chirand and regional comparators	Plant/mineral processing	Which cereal or preparation without residues
Pottery forms	Chirand; Chechar; Oriup; Panda	Containment, heating, serving, storage possibilities	Vessel contents from shape alone
Pits / jars / bins	Regional comparators; variable local evidence	Possible storage where context supports it	Surplus size, taxation or household wealth

CHAPTER 5 — ENVIRONMENT, MOBILITY AND SETTLEMENT

5.1 Scope: settlement was an environmental negotiation

A settlement map is not simply a map of where people preferred to live. In the Himalayan foreland and Middle Ganga plain, the ground itself was repeatedly remade by rivers, sediment, monsoon floods, groundwater, erosion and local tectonic movement. The same processes that threatened houses could renew fields, create fisheries, open transport corridors or bury older occupations. This chapter therefore treats settlement as a negotiation among several changing variables rather than as a one-time choice of a “good” site. The purpose is not to make environment a deterministic cause of culture. Human knowledge, labour, storage, social cooperation, route networks and technology all affected how communities used a given surface.

5.2 A flat plain contains many different surfaces

At regional scale north Bihar and the adjoining Nepal Tarai appear extremely flat, but that appearance conceals differences that mattered greatly at household scale. Natural levees stand slightly above adjoining backswamps; abandoned channels become linear depressions; crevasse splays and bars create locally raised sandy ground; older alluvial surfaces may drain differently from younger floodplain deposits; and fan surfaces grade southward from the Himalayan front. Sinha’s work on the Gandak–Kosi interfan and later studies of the Gangetic plains emphasize this geomorphic diversity. A height difference of only a metre or two can change the duration of waterlogging, the accessibility of a well, the suitability of a crop, and the probability that a house floor remains dry during ordinary floods (Sinha 1995, 1996; Sinha et al. 2005).

5.3 Rivers of north Bihar do not all behave alike

Sinha and Friend classified rivers of the northern Bihar plains by source area—mountain-fed, foothills-fed, plains-fed and mixed-fed—and showed that their hydrology and sediment behaviour differ (Sinha and Friend 1994). A large Himalayan river brings a different combination of discharge, sediment calibre and seasonal variability from a smaller plains-fed stream. This matters for settlement history because “living by a river” could mean living beside a braided trunk channel, an anabranching foothills-fed river, a smaller meandering stream, or an abandoned channel that retained water after the active course moved elsewhere. The economic possibilities and risks were therefore not uniform across the floodplain.

5.4 Megafans and interfan plains created different settlement problems

The Gandak and Kosi have built enormous sedimentary bodies commonly described as megafans, while the terrain between them includes interfan tracts crossed by rivers such as the Bagmati and Burhi Gandak. Megafans are not static cones. Their surfaces contain active and abandoned channels, splays, flood basins and soils of different ages. Interfan plains likewise record channel avulsion, overbank sedimentation and waterlogging. Settlement history must therefore be reconstructed at the scale of individual landforms and local sequences, not by assuming that one river model describes the whole of Mithila and Vajji.

Figure 16 — Landscape units and settlement opportunities across the Himalayan foreland-alluvial plain

Figure 16 — Landscape units and settlement opportunities across the Himalayan foreland-alluvial plain. The transect is schematic and not drawn to scale.

5.5 The Gandak megafan: long-term shifting changed soil and settlement surfaces

Mohindra, Parkash and Prasad used geomorphology and soil development to argue that the Gandak channel shifted substantially eastward during the later Holocene, producing a sequence of geomorphic surfaces and soils of different ages (Mohindra, Parkash and Prasad 1992). Their reconstruction is important here not because every number must be transferred directly into archaeological chronology, but because it demonstrates that the apparent plain contains a history. Older surfaces may have had longer periods for soil development and settlement stability; younger surfaces may contain fresher sediment, abandoned channels and more recent disturbance. Archaeological survey that ignores landform age risks comparing areas with very different probabilities of preserving or exposing sites.

5.6 The Kosi megafan: do not repeat the simple westward-sweep story

The Kosi is often described as having migrated steadily westward across more than a hundred kilometres before being embanked. Chakraborty and colleagues re-examined historical maps and near-surface sediments and challenged that simple unidirectional narrative. They argued that the historical channel record is better understood as oscillation and random nodal avulsion across different fan lobes rather than a continuous sweep (Chakraborty et al. 2010). For settlement history the methodological lesson is decisive: abandoned channels cannot automatically be placed in a neat west-to-east or east-to-west chronological ladder. Each palaeochannel and occupation surface requires independent dating and stratigraphic control.

5.7 The Bagmati shows how often a river can reorganise an inhabited plain

The Bagmati provides a well-studied example of a hyperavulsive, anabranching river. Jain and Sinha reconstructed repeated major and minor avulsions over the historical period and related them to overbank flooding, high wash load, channel aggradation, local slope and tectonic influences (Jain and Sinha 2003, 2004, 2005). The lesson extends beyond modern flood hazard. A settlement beside one branch might later stand beside an abandoned channel; a route crossing could become unusable; a former wet depression might receive sediment and become cultivable; another tract could become waterlogged. Settlement continuity at a named locality therefore need not imply continuity of the same river relation.

5.8 Aggradation raises channels as well as land

Overbank deposition can slowly raise floodplain surfaces, but sediment accumulation within and beside a channel can also reduce the relative depth of the channel and make avulsion more likely. Sinha's work on

northern Bihar emphasizes the combination of high sediment loads, rapid aggradation and low regional gradients (Sinha 1998). Communities living in such settings could benefit from fine silt deposited on fields while simultaneously facing increasing flood or channel-shift risk. The same sediment is thus both productive resource and geomorphic hazard.

Figure 17 — Four fluvial processes that repeatedly reorganise settlement landscapes

Settlement consequences could include field loss, improved silt, altered crossings, burial of sites, or relocation—often in combination.

Figure 17 — Four fluvial processes that repeatedly reorganise settlement landscapes: lateral migration, cutoff, aggradation and avulsion.

5.9 Natural levees offered advantages, not immunity

Natural levees form where coarser suspended sediment is dropped close to a channel during overbank floods, leaving slightly raised strips beside the river. Such surfaces can drain faster than adjacent flood basins and may therefore attract paths, fields and habitation. Yet a levee is created by flooding and remains part of the floodplain. It can be cut by bank erosion, breached by crevasse channels, or bypassed after avulsion. A raised settlement surface should therefore be understood as a risk-management choice within a floodplain, not as withdrawal from the floodplain.

5.10 Oxbows, abandoned channels and backswamps were productive spaces

The low areas between active channels preserve water, fish, aquatic plants, reeds, clay and grazing opportunities. Chapters 3 and 4 showed that early agrarian economies did not rely on fields alone. Wetlands extended that mixed economy into the settlement landscape. An abandoned channel could serve as a water source or fishery long after it ceased to carry the main river. Conversely, prolonged waterlogging could restrict house construction and some crops. The economic value of a wetland therefore depended on season, access, technology and household needs.

5.11 Flood was not one event category

Historical language often collapses several processes into “flood.” For settlement analysis it is useful to separate at least overbank inundation, prolonged waterlogging, bank erosion and avulsion. Ordinary inundation may leave fine sediment without destroying a settlement; bank erosion can physically remove the archaeological record; waterlogging can make an otherwise undamaged locality temporarily unusable; avulsion can transfer the main river into an entirely new corridor. These distinctions prevent modern disaster vocabulary from being imposed indiscriminately on archaeological deposits.

5.12 Sediment could improve a field and bury a house

Fresh alluvium may replenish nutrients or create new cultivable surfaces, but deep sand deposition can also render fields temporarily less productive. Fine overbank silt, coarse crevasse deposits and channel sands have different effects. Archaeologically, the same deposit may seal a floor and preserve it from later disturbance. Thus a sediment layer is not merely “flood damage”: it can be a record of the event that ended one occupation surface and created the substrate for another.

5.13 Soil age matters to archaeological expectations

The Gandak megafan study by Mohindra and colleagues linked geomorphic surfaces to differences in soil development. The broader implication is that older stable surfaces have had more time for pedogenesis, cultivation, erosion and repeated occupation, whereas young surfaces may bury older land beneath metres of alluvium. Survey intensity should therefore be adjusted to landform history. A dense scatter on one old surface and few sites on a recently aggraded tract cannot be read directly as a prehistoric population map.

5.14 Tectonics belongs in the settlement story, but not as a universal explanation

The Himalayan foreland is tectonically active, and Jain and Sinha documented channel anomalies in the Bagmati basin associated with subsurface structural controls and changes in local slope (Jain and Sinha 2005). Earthquakes can alter gradients, liquefy sediment, damage settlements and modify drainage, but not every channel shift should be attributed to tectonics. Hydrology, sedimentation and local topography also matter. The responsible historical formulation is therefore multi-causal: tectonic deformation can change the conditions under which fluvial processes operate.

5.15 Monsoon variability altered both opportunity and risk

The annual monsoon concentrated water and sediment delivery into a seasonal cycle. Stronger or differently distributed rainfall could increase flood frequency, bank erosion or channel activity; weaker phases could reduce surface water while exposing new bars and floodplain surfaces. Long-term alluvial sequences in the Ganga plain preserve responses to changing monsoon conditions, but settlement history should not assume that every cultural transition was climate-driven. Climate modifies a field of possibilities that communities respond to through cropping, storage, mobility, exchange and site choice.

Figure 18 — Archaeological visibility is produced by geomorphology as well as human occupation

The archaeological map records visibility as much as original settlement density.

Active floodplains can hide deeply buried occupations while eroding others into view; “no site found” is therefore not equivalent to “no settlement existed.”

Figure 18 — Archaeological visibility is produced by geomorphology as well as human occupation.

5.16 Archaeological visibility is a geomorphic process

One of the most important consequences of an active alluvial landscape is methodological. A village may disappear from the modern surface because it was buried beneath later sediment rather than because the area was abandoned. Elsewhere, bank cutting or gully erosion may expose artefacts and make a site unusually visible. Corvinus's work in Nepal repeatedly benefited from erosion that exposed archaeological material, while the deep alluvium of the Gangetic plain can conceal occupations. The archaeological map therefore records a history of discovery conditions as well as a history of settlement (Corvinus 2007; Darnal 2016).

5.17 Burial can preserve what surface exposure destroys

Rapid burial may protect floors, hearths, charred seeds or bones from later ploughing and weathering. The same process can place them beyond the reach of ordinary surface survey. Conversely, an eroding mound may yield abundant artefacts while losing stratigraphic context. This is why settlement counts must be accompanied by information about geomorphic setting, sediment depth and discovery method. "More sites" may partly mean "more visible sites."

5.18 River-cut mounds and terraces deserve different expectations

Chirand, Chechar, Panda and Oriup occupy different local settings, and their archaeological sequences cannot be reduced to one settlement template. A mound near a major river can preserve repeated occupations because people returned to or rebuilt on a relatively favourable elevation. A terrace-edge workshop such as Patu in eastern Nepal represents another relationship to topography and raw material. Comparing these places is useful only when the differences in landform, function and chronology remain explicit.

5.19 Sedentary settlement did not mean a fixed productive territory

A house can remain in one village while fields shift among available plots, cattle move to seasonal grazing, fishers use changing channels, fuel collectors visit forest margins and traders travel to other settlements. The mixed economies reconstructed in Chapters 3 and 4 therefore imply routine mobility within sedentary life. Archaeological categories such as "village" and "site" can obscure this wider taskscape if they are treated as self-contained economic units.

5.20 Seasonal mobility reduced risk

Floodplain households could respond to seasonal changes by moving activities rather than residences. Wet-season fishing, dry-season grazing on exposed surfaces, collection of reeds or fuel, and cultivation in differently drained plots spread risk across the landscape. The specific calendar varied locally, and the evidence does not permit a single prehistoric schedule. What can be defended is the structural point: diversified subsistence made spatial flexibility economically valuable.

Figure 19 — Mobility without a false sedentary/nomadic binary

A village can be sedentary while households, herds, fishers, traders and fields remain mobile across a changing floodplain.

Figure 19 — Mobility without a false sedentary/nomadic binary: daily movement, seasonal resource use, exchange, temporary relocation and permanent site shift form a continuum.

5.21 Paths and crossings moved with the rivers

Rivers were transport corridors but also obstacles. Fords, ferries and shallow crossings could shift as channels migrated or deepened. A settlement's advantage as a crossing point was therefore historically contingent. Routes often followed levees or other better-drained ground, while wetlands could redirect travel. These changing connections help explain why settlement importance cannot be inferred solely from straight-line distance between archaeological sites.

5.22 Exchange linked contrasting ecological zones

The alluvial plain lacked many stone and metal raw materials that appear in archaeological assemblages. Movement or exchange connected floodplain settlements to foothills, plateau margins and more distant geological sources. River routes were one component of that circulation. The contrast between resource-rich wetlands and relative scarcity of knappable stone in much of the alluvium created reasons for mobility even when food production was locally secure.

5.23 Relocation need not mean social collapse

When erosion removes a settlement edge or a channel occupies former fields, households may rebuild nearby while maintaining kin, ritual and economic connections. Archaeologically this can look like abandonment of one mound and foundation of another. Without independent evidence, such movement should not be labelled invasion, depopulation or “collapse.” In a mobile floodplain, relocation can be a normal strategy of continuity.

5.24 Eastern Nepal: the Sapta Kosi fan extends the same problem across the modern border

The Sapta Kosi forms a large alluvial fan after leaving the Siwalik Hills. Thakur and Tamrakar described Holocene fan deposits in eastern Nepal ranging from gravel to fine sand and mud and emphasized channel shifting, flooding, erosion and waterlogging as active geomorphic problems (Thakur and Tamrakar 2002). These observations matter to a history of Mithila in Nepal because the modern international boundary does not divide the sedimentary system. Northern and southern parts of the foreland must be analysed together while keeping their political histories distinct.

5.25 Patu and the Rato Khola: foothill terraces offered a different landscape from the deep plain

Corvinus's Patu industry in Mahottari was found on older terrace surfaces near the Rato Khola where erosion exposed abundant lithic material. The foothill/Siwalik setting offered quartzite cobbles and terrace surfaces unlike the fine alluvial tracts farther south. Patu therefore demonstrates both environmental diversity and discovery bias: the same erosion that threatens a surface can reveal a prehistoric workshop. It should not be used as evidence that the contemporary political or cultural identity of Mithila existed in the early Holocene; it is evidence for human use of a landscape that later formed part of the Mithila region (Corvinus 1987, 1989, 2007).

5.26 Anga and the eastern plain: rivers connected rather than isolated the Bhagalpur zone

Oriup and Champa belong to a different part of the river system from the north Bihar fan-interfan tract, but they reinforce the importance of river corridors. The Ganga and its tributaries connected fishing grounds, settlements and exchange routes through the Bhagalpur region. Chapter 4 already identified direct fishing technology at Oriup. Chapter 5 adds the spatial point: aquatic resources and movement along the river were part of settlement logic, while channel change could alter access and site preservation.

5.27 Population estimates require more than site counts

An increase in the number of known Chalcolithic or early historic sites may reflect genuine demographic growth, but it can also reflect longer occupation, larger settlements, better archaeological visibility or uneven survey. Settlement size, duration, contemporaneity and buried-site probability all matter. This chapter therefore avoids converting raw site totals into population figures. Demographic reconstruction becomes stronger only when survey coverage, chronology and landform history are controlled together.

5.28 Conclusion: settlement was durable because it could move

The apparent paradox of the alluvial plain is that long-term human continuity depended partly on flexibility. Rivers supplied water, fish, fertile sediment and routes, but they also eroded, flooded and shifted. Communities managed this uncertainty through location choices, diversified land use, seasonal movement, exchange and, when necessary, relocation. The historical unit is therefore not the immobile village but the settlement landscape: houses, fields, wetlands, paths, grazing areas, channels and remembered places that changed in relation to one another. This conclusion prepares the transition from prehistoric environmental adaptation to the more densely documented social and economic institutions of later chapters.

Table 5.1 — Environmental setting and settlement implications

Landscape / process	Potential advantages	Potential costs	Historical caution
Natural levee / raised bank	better drainage; route access; proximity to water	bank erosion; crevasse flooding; channel migration	raised ground is not flood-free ground
Backswamp / oxbow	fish, reeds, water, grazing, clay	waterlogging; mosquitoes; limited house sites	wetland value varies by season and technology
Older alluvial surface	longer soil development; relative stability	greater distance from active water in some settings	older surface does not automatically mean older occupation

Landscape / process	Potential advantages	Potential costs	Historical caution
Young fan / splay surface	fresh sediment; new land; changing channels	erosion, sand deposition, unstable drainage	low site visibility may reflect burial
Foothill / terrace edge	stone raw material; drainage; varied ecotones	erosion; local tectonic and slope hazards	cannot be treated as identical to low alluvial plain
Avulsion corridor	new water and sediment pathway	rapid relocation of channel and routes	abandoned channels need independent dating
Interfan plain	mixed river and wetland resources	frequent overbank flooding and waterlogging	small rivers can be highly mobile too

PART II

EARLY HISTORIC SOCIETY: VIDEHA, VAJJI AND ANGA

Chapters 6–18

CHAPTER 6 — THE SECOND URBANISATION

6.1 Scope: “second urbanisation” is a shorthand, not a single event

The expression “second urbanisation” is commonly used for the growth of towns, cities, states, specialised production and long-distance exchange in northern India during the early first millennium BCE, especially in the Ganga plains. It is useful only if it is not turned into a fixed date or a single-cause event. Archaeological sequences differ from site to site; some settlements grew gradually from earlier agrarian occupations, some acquired fortifications or durable architecture at different times, and some remained rural while participating in increasingly complex exchange networks. This chapter therefore uses “second urbanisation” as a regional process whose components became visible at different rates rather than as a moment when villages suddenly became cities (Allchin 1995; Sawant and Shete 2016).

6.2 What makes the process “second”

The term contrasts early historic urban growth with the much earlier cities of the Indus or Harappan civilisation. It does not imply direct institutional continuity between those urban traditions and the Middle Ganga cities. The long chronological and geographical gap requires independent explanation. The “second” urbanisation is thus a historiographical label for a renewed and differently organised urban process in the first millennium BCE. Its archaeological signature includes settlement concentration, fortifications, specialised crafts, exchange, coins, increasingly durable construction and the emergence of political and religious institutions, but the exact bundle varies among sites.

6.3 The Middle Ganga plain was not empty before cities

Chapters 2–5 demonstrated long sequences of hunting, farming, animal keeping, fishing, craft production and riverine mobility before the early historic period. Chirand, Chechar, Panda, Oriup and other sites already show communities capable of managing surplus, mixed subsistence and exchange. Urban growth must therefore be understood as a reorganisation and intensification of existing social landscapes, not as civilisation arriving in an unoccupied forest. This point also corrects older models in which dense forest was imagined as the single barrier that iron axes suddenly removed.

6.4 Iron mattered, but it was not an urban switch

Iron technology expanded the range and durability of tools and weapons and eventually contributed to cultivation, carpentry, construction and political power. Yet the archaeological chronology does not support a simple equation “iron = cities.” Iron appears in the Ganga plains before the mature early historic urban pattern. The long interval between initial iron use and large urban centres means that technology had effects only through labour organisation, agrarian production, exchange, institutions and demographic concentration. IGNOU’s archaeological synthesis explicitly cautions that iron sustained urbanisation but cannot by itself explain it; this chapter adopts that multi-causal position.

6.5 Agriculture supplied the indispensable rural base

Urban consumers had to be fed. Archaeobotanical evidence from the Ganga plains shows long-standing cultivation of rice together with other cereals and pulses before the NBPW horizon. Intensification could include extension of cultivation, more dependable storage, greater labour mobilisation and stronger flows of produce toward non-farming consumers. None of these processes requires every farmer to use an iron

ploughshare. The key historical change is the capacity of agrarian landscapes to support larger concentrations of people whose work increasingly included administration, trade, craft, warfare or religious service.

6.6 Surplus was social, not simply biological

A good harvest becomes an urban resource only if grain can be stored, moved and claimed. Households, chiefs, assemblies, rulers, merchants, monasteries and other institutions could redirect produce through gifts, tax, tribute, rent, exchange or ritual obligation. “Surplus” therefore should not be imagined as grain automatically left over after subsistence. It was created and channelled through social relations. This distinction is essential for a socio-economic history because it links agricultural productivity to power and institutions without assuming that state formation was mechanically produced by crop yields.

Figure 20 — Urbanisation as a convergence rather than an iron-triggered event

No single cause is sufficient: “second urbanisation” names a convergence of processes.

Figure 20 — Urbanisation as a convergence rather than an iron-triggered event. The components could develop at different rates and reinforce one another.

6.7 Northern Black Polished Ware: an important marker, not the definition of urbanism

Northern Black Polished Ware (NBPW) is a distinctive fine ceramic tradition whose distribution has long been used to organise early historic chronology. Its lustrous surface, limited production and wide circulation make it valuable for studying cultural contact, exchange and status. Recent archaeological summaries stress, however, that NBPW is an artefact class rather than a synonym for a city (Kanungo et al. 2021). It can occur in settlements of different scale and function, while urban features may develop before or after particular ceramic horizons. This volume therefore uses NBPW as one chronological and economic indicator among several.

6.8 NBPW chronology is not a universal fixed bracket

Published dates for NBPW vary by site and by the dating method used. Older schemes often placed its main beginning around the sixth century BCE, whereas some excavated sequences and later reviews allow earlier starts in particular contexts. The correct method is therefore site-specific: stratigraphy, associated ceramics, radiocarbon dates where available, coins and structural sequence must be assessed together. The chapter avoids assigning every NBPW sherd in Bihar to an identical century merely because the pottery shares a technological style.

6.9 What archaeologists should require before calling a settlement urban

Size is important but insufficient. A large mound can represent long occupation rather than a large simultaneous population. Fortification may indicate defence, display, flood management or political control, but a wall alone does not create an urban economy. Stronger diagnoses combine several lines of evidence: dense and durable buildings, specialised craft areas, public or institutional structures, water management, streets or drains, coinage and exchange goods, a settlement hierarchy with smaller dependent places, and evidence that substantial numbers of inhabitants were supported by production beyond their own household subsistence.

Figure 21 — Evidence bundle for identifying early urban settlements

A pottery type alone does not make a city.

Urban diagnosis is strongest when several independent indicators converge in stratified context.

Figure 21 — Evidence bundle for identifying early urban settlements. No single indicator, including NBPW, is sufficient on its own.

6.10 Vaishali: archaeology and historical identification must be kept distinct

Vaishali is central to the literary histories of Vajji and the Licchavis, but archaeology must be read independently of those texts before the two records are compared. The ASI's Patna Circle lists the excavated Buddha relic stupa at Harpur Basant and the large mound conventionally known as Raja Vishal ka Garh among the protected remains. The relic-stupa excavation yielded a relic casket and other objects; the ASI assigns its innermost stupa to approximately the fifth century BCE. At Raja Vishal ka Garh, excavation across the rampart identified several later defensive phases, while finds from the wider site range from the sixth century BCE onward. These data confirm a major early historic settlement complex; they do not by themselves prove that a particular mound was a republican assembly hall simply because of its modern name.

6.11 Vaishali's importance was regional, not only political

A centre capable of sustaining ritual establishments, craft activity, markets, visitors and political gatherings depended on a broad supporting landscape. The later textual image of Vaishali as a wealthy place is therefore best tested against settlement archaeology, transport routes and material culture rather than repeated as description. Its location in the north Bihar plain connected it to riverine and overland routes, to agrarian producers and to the wider network that linked the Ganga valley with the Himalayan foreland.

Urbanity here should be understood as the concentration of functions as much as the concentration of buildings.

6.12 Raja Vishal ka Garh and the danger of function-by-name

Archaeological place-names frequently preserve later memory. A mound called a “garh,” “palace” or “assembly” may indeed overlie an ancient fortified or public area, but the name cannot establish the original function of every structural phase. The three defensive phases reported by the ASI at Raja Vishal ka Garh belong to Sunga, Kushana and early Gupta periods, later than the sixth-century BCE horizon represented among the site’s finds. The chronological mismatch is a useful warning: the political importance of early Vaishali is not evidence that every surviving rampart belongs to the Vajjian republic.

6.13 Chirand: a rural–riverine settlement inside the urbanising economy

Chirand is especially valuable because it shows that “urbanisation” also transformed places that were not necessarily cities. Indian Archaeology 1962–63 reported a historical Period II, approximately 600–100 BCE, marked by the advent of iron and NBPW together with grey ware, terracotta figurines, beads and other objects. The sequence follows much earlier Neolithic and Chalcolithic occupation. Chirand therefore demonstrates continuity through a changing material economy: a long-lived riverine settlement became connected to early historic technologies and exchange without needing to be reclassified as an urban capital.

6.14 Rural sites were active participants, not passive suppliers

The countryside contained craft workers, traders, fishers, herders and households with their own consumption choices. Some rural settlements acquired fine pottery, beads, coins or iron tools through exchange. Others may have specialised in products sent to larger centres. Urban and rural were therefore relational categories. The same household could sell grain, obtain a manufactured implement, visit a religious centre, pay an obligation to a political authority and participate in a periodic market. Urban growth intensified these connections rather than replacing local economies.

6.15 Fortification was labour made visible

Large ramparts required organised labour, planning and repeated maintenance. Their social meaning lies not only in military defence but in the capacity to mobilise people and materials. Mud ramparts could consume enormous volumes of earth; brick walls required fuel, clay preparation, transport and specialist knowledge. Fortifications also marked boundaries and could structure gateways, movement and taxation. The appearance of defended centres is therefore evidence for collective or coerced labour and institutional capacity, though the political form behind that labour must be established separately.

6.16 Champa: Anga’s archaeological sequence is indispensable

The excavations at Champa, near modern Bhagalpur, prevent the history of “second urbanisation” from being reduced to the north Bihar–Magadha axis. Exploration reported black-and-red ware in lower deposits and NBPW in upper levels, while excavation revealed a substantial mud fortification and later brick construction. Indian Archaeology 1970–71 associated the rampart phase with black-and-red ware and NBPW and recorded ring-wells and other material. Subsequent seasons refined the sequence, and the 1975–76 excavation exposed multi-room brick structures assigned to the late NBPW period. Champa thus provides direct archaeological evidence for a fortified and architecturally complex early historic centre in the Anga region.

6.17 Champa's rampart did not appear from nothing

The Champa sequence contains ceramic traditions that precede or overlap the NBPW horizon. This is important because it supports a developmental rather than replacement model. Early historic urban features emerged on a settlement history already linked to the Ganga corridor. The relationship among lower black-and-red ware deposits, NBPW horizons, rampart construction and later brick buildings must remain stratigraphic: they should not be collapsed into one undifferentiated “Anga city” phase.

6.18 Ring-wells, drains and water management: ordinary infrastructure matters

Urban history is often written from walls, palaces and monuments, but small infrastructure may reveal more about daily density. Ring-wells, drains, paved floors and waste-disposal arrangements become increasingly important where many households occupy restricted space. Champa's excavations reported ring-wells in early historic contexts. Such installations do not automatically prove municipal government, but they indicate investment in water or sanitation technologies that are especially useful in dense settlements.

Figure 22 — A conceptual Middle Ganga-Anga settlement network

Urban growth was regional: towns depended on villages, routes, river crossings and other centres.

Figure 22 — A conceptual Middle Ganga-Anga settlement network. The diagram shows functional interdependence, not a reconstruction of exact ancient roads or geographic coordinates.

6.19 Craft specialisation increased the number of non-farming livelihoods

Potters, metalworkers, bead makers, carpenters, builders, textile workers, ivory and bone workers and other specialists could operate at several scales. Some production remained household-based; other work required workshops, furnaces, standardised products or access to imported raw materials. Urban centres concentrated consumers and institutions able to support specialists, while regional exchange connected craftsmen to villages and distant resources. The evidence should therefore be read as a continuum from part-time household production to highly specialised craft rather than as an abrupt division between “peasant” and “artisan.”

6.20 Iron technology widened possibilities for craft and construction

Iron's urban significance was broader than forest clearance. Nails, clamps, knives, axes, chisels and other tools affected carpentry, building and maintenance. Archaeometallurgical work on an early historic iron nail from Balirajgarh, for example, demonstrates sophisticated forging and work-hardening in the Middle Ganga region by roughly 2,300 years ago (V. Singh and M. R. Singh 2019). Such evidence is important because it

shifts discussion from abstract claims about an “iron revolution” to actual manufacturing knowledge and particular artefacts.

6.21 Exchange expanded through multiple media

Markets could operate through barter, weighed metal, coins, credit, gifts and institutional redistribution. Punch-marked coins become significant in early historic contexts, but monetisation was neither instant nor complete. A coin in an excavation proves that metallic currency reached that context; it does not prove that every transaction in the settlement was monetised. The spread of fine ceramics, beads, metals and other non-local goods provides an independent record of exchange alongside coinage.

6.22 NBPW itself records circulation and selective consumption

Because NBPW was produced in limited quantities and circulated widely, its presence can illuminate exchange and social differentiation. Kanungo and colleagues emphasise its value for studying contact and hierarchy. Yet the ware should not be treated automatically as “elite tableware” in every context: vessel form, quantity, associated finds and depositional setting matter. A few sherds in a rural settlement may reflect participation in regional circulation rather than the presence of an urban elite.

6.23 Roads and rivers created a network, not a chain of isolated capitals

Vaishali, Rajagriha, Pataliputra and Champa occupied different ecological and political settings, but their growth depended on movement among settlements. The Ganga and tributaries supported boats and ferry crossings; overland paths connected natural levees, market places and political centres. Routes changed with river migration and political security. It is therefore more accurate to imagine overlapping corridors and nodal places than a fixed road map projected backward from later itineraries.

6.24 Religious institutions were also urban-economic actors

Buddhist and Jain texts foreground teachers, monks, nuns, merchants and donors moving among major settlements. Archaeology adds monasteries, stupas, reliquaries and craft objects. Religious institutions drew food, cloth, building materials and donations from lay communities while also attracting travellers and concentrating exchange. Their economic role should neither be ignored nor reduced to commerce: ritual, learning, prestige, redistribution and hospitality all formed part of the urban social economy.

6.25 Political institutions concentrated resources

Monarchies and non-monarchical polities could both support urban centres. Fortifications, officials, armed retainers, assemblies and public ceremonies drew resources toward political nodes. The old opposition between “republic” and “monarchy” does not by itself explain why one settlement became urban. What matters materially is the capacity of institutions to mobilise labour, collect or redirect produce, regulate routes and maintain public works. The specific constitution of Vajji is treated in Volume I and later chapters; here the focus is the socio-economic consequence of institutional concentration.

6.26 Literacy belongs to the later visible phase, not to the beginning by assumption

Urbanisation often promotes record keeping, but the chronology of writing must be established from inscriptions and securely dated objects. The presence of states, trade or NBPW does not allow historians to assume widespread literacy at the beginning of the urban process. Brahmi and Kharoshthi inscriptions

become archaeologically visible in later first-millennium BCE contexts. Earlier administration may have used perishable media or non-written practices, but such possibilities cannot be converted into evidence without surviving traces.

6.27 Social inequality became more materially visible

Differences in house size, access to fine goods, jewellery, coinage, craft products and burial or ritual expenditure can provide clues to inequality, but no single object yields a caste or class identity. Urban settings likely intensified disparities because they concentrated political authority, merchants, specialists, dependants and labourers. Yet the archaeological record usually reveals unequal consumption more readily than it reveals the legal categories by which people understood that inequality. Later textual classifications must therefore not be retrojected automatically into every excavated household.

6.28 Women's labour is structurally necessary but archaeologically undernamed

Food processing, textile production, household management, childcare, exchange and ritual work were essential to sustaining dense settlements, yet artefacts rarely identify the sex of their users securely. Grinding stones, spindle whorls, cooking vessels or ornaments cannot simply be labelled “women's objects.” A socio-cultural-economic history must make household labour visible while keeping inference disciplined. Gender becomes more historically specific only when archaeological context can be combined with texts, inscriptions or osteological evidence.

6.29 Nepal-side Mithila: do not export the Bihar sequence without evidence

The political and cultural history of Mithila crosses the modern India–Nepal border, but the archaeological visibility of early urbanisation is uneven. At present, the well-published sequences used in this chapter come primarily from Bihar and the Middle Ganga plain. The Nepal Tarai contains important early historic sites, but many lie outside the historical Mithila focus and cannot simply be used as substitutes for Janakpur or eastern Madhesh. Until comparable excavated sequences are available, the correct conclusion is not “no urbanisation,” but “insufficient site-specific evidence to assign the same sequence with equal confidence.”

6.30 Conclusion: cities were produced by relationships

The second urbanisation was not a ceramic phase, an iron revolution or the automatic consequence of state formation. It was a long regional transformation in which agriculture supported larger non-farming populations; institutions mobilised resources; crafts became more specialised; settlements were fortified and internally reorganised; exchange networks widened; and some places accumulated political, commercial and ritual functions. Vaishali and Champa illustrate different trajectories, while Chirand shows how long-lived rural settlements participated in the same changing economy. The key analytical unit is therefore the network linking town and countryside. Chapter 7 turns from this urbanising landscape to the household, kinship and family relations that organised everyday social reproduction.

Figure 23 — Rural-urban interdependence in the early historic economy

Urbanisation reorganised exchange; it did not replace the countryside.

Figure 23 — Rural-urban interdependence in the early historic economy. Flows were reciprocal and could include produce, labour, taxes, manufactured goods, markets and institutional services.

Table 6.1 — Selected archaeological anchors for the urbanising Middle Ganga–Anga region

Place / context	Material indicators	What they support	What they do not prove by themselves
Vaishali / Harpur Basant and Raja Vishal ka Garh	relic stupa; early historic finds; later rampart phases	major ritual and settlement complex with long occupation	that every named mound had the political function assigned by later tradition
Chirand, Period II	iron; NBPW; grey ware; terracotta figurines; beads	participation of a long-lived riverine settlement in early historic material networks	that Chirand was an urban capital
Champa lower-to-NBPW sequence	BRW below; NBPW above; mud fortification	development of a fortified early historic centre in Anga	that all rampart phases belong to one political moment
Champa late NBPW structures	multi-room brick buildings; brick floors; ring-wells in related seasons	dense durable construction and household / infrastructural investment	a specific municipal constitution or population total
NBPW distribution	fine polished pottery circulated widely	exchange, chronology and selective consumption	urban status of every site where sherds occur
Iron artefacts	tools, weapons, nails, craft evidence	technological capacity supporting farming, construction and craft	a single-cause “iron revolution” that automatically produced cities

CHAPTER 7 — HOUSEHOLD AND FAMILY IN EARLY HISTORIC SOCIETY

7.1 Scope: household, family and lineage are not synonyms

A history of family cannot begin by assuming that every person lived in a nuclear family, a “joint family,” or a fixed patrilineage. These are analytical labels, not archaeological finds. A household is first of all a unit of co-residence, provisioning, labour and care; family describes relationships created through birth, marriage, adoption and social recognition; lineage refers to descent remembered across generations; and political clan membership may operate at a still larger scale. Early historic sources use several terms—among them *kula*, *gotta/gotra*, *ñāti* and *gahapati*—whose meanings overlap only partly and vary by textual setting. This chapter therefore reconstructs social relations by scale rather than treating every kin term as evidence for one timeless Indian family form (Thapar 1999; Chakravarti 1987; Olivelle 2019).

7.2 The evidence problem is unusually severe

Domestic life leaves abundant material traces—cooking vessels, hearths, grinding stones, storage facilities, ornaments, tools and architectural spaces—but these objects rarely identify kinship directly. Texts offer names for relatives, marriage rules, household heads and dependants, yet they are selective: Buddhist texts often foreground donors, renouncers and encounters around monasteries; Brahmanical legal texts prescribe ideals for particular social groups; later narratives may preserve older motifs while reflecting later social assumptions. The correct method is therefore triangulation. Archaeology can show how people lived together; texts can illuminate categories and norms; inscriptions can sometimes identify donors and relationships; none should be forced to answer questions beyond its evidentiary scale.

7.3 Domestic architecture is evidence for co-residence, not a family tree

Multi-room buildings at early historic Champa and domestic features at other Middle Ganga sites demonstrate investment in bounded residential space, water facilities and repeated household activity. They can sometimes reveal cooking zones, storage, craft work or rebuilding. They cannot by themselves tell us whether residents were parents and children, brothers with their spouses, unrelated workers, tenants, servants or a changing combination of these. A large house is not automatically a “joint family house,” just as a small structure is not automatically a nuclear household. Architectural interpretation must remain open to household fission, seasonal absence, lodgers, servants and changing life cycles (Archaeological Survey of India 1970–76; Allchin 1995).

7.4 Household archaeology works through repeated activity

The most convincing domestic identification comes from bundles of evidence: hearths or ovens, food-processing tools, storage jars, floor renewal, refuse disposal, spindle whorls or craft debris, water installations and repeated repair. Such combinations indicate that a place sustained everyday life over time. Even then, they reveal activity groups more securely than genealogies. This distinction is crucial for Mithila, Vajji and Anga because later social memory is rich in kinship narratives; archaeological house plans must not be retrofitted to match those narratives merely because both concern “families.”

Figure 24 — Evidence layers for reconstructing household and family
Household history is strongest when independent kinds of evidence converge.

No layer alone reveals a complete family structure; each has a different bias and scale.

Figure 24 — Evidence layers for reconstructing household and family. Each source type records a different aspect of domestic and kin life; convergence is stronger than any single indicator.

7.5 The household was a production as well as a consumption unit

Early historic households cooked and consumed food, but many also processed grain, spun fibre, maintained animals, repaired tools, stored produce and participated in craft production. The relative importance of each activity varied between rural settlements, market towns and larger urban centres. Household labour therefore linked agriculture to urbanisation: grain might be cultivated outside a town, processed within a household, taxed or exchanged, and redistributed through markets or religious institutions. The household is consequently best understood as a node connecting land, labour, consumption and exchange rather than as a purely private sphere.

7.6 Care work made settlement continuity possible

Children had to be fed and taught; the ill and elderly required support; births and deaths reorganised labour; absences through trade, war, pilgrimage or renunciation changed who remained at home. None of this is easily quantified, yet it is structurally necessary for understanding long-lived settlements. Social reproduction—cooking, cleaning, child care, nursing, maintaining clothing, transmitting skills and sustaining relationships—was economic work even when ancient texts did not count it as a market transaction. A socio-cultural-economic history must therefore recover care as a historical process without pretending that archaeology can always identify who performed each task.

7.7 Gahapati was a social category, not a synonym for every married man

Pāli sources frequently use gahapati for a lay household head, and scholarship on early Buddhism has shown that the term often carries associations of property, productive resources and local standing. Chakravarti's study of early Buddhist society treats the gahapati as a significant category in the agrarian and urban social order rather than simply as "any householder" (Chakravarti 1987). The term may appear beside merchants, landholders and substantial donors. It should therefore not be used to reconstruct every poor or

dependent household, nor should it be equated mechanically with the later religiously theorised Sanskrit *grhastha*.

7.8 Gahapati and *grhastha* belong to different conceptual histories

Recent scholarship has emphasised that *grhastha* became a religiously charged concept defined partly in relation to renunciation, whereas ancient Indian languages possessed several more ordinary terms for householders and household heads (Olivelle 2019). This matters methodologically. A Pāli narrative about a *gahapati* in the age of urbanisation cannot simply be translated into a fully developed four-*āśrama* model. The household was already economically central, but later religious systematisation should not be projected backward as if it were the universally shared social grammar of sixth- or fifth-century BCE Vajji and Anga.

7.9 Kinship vocabulary records several overlapping scales

Kula may designate a family, house, descent group or status-bearing line depending on context; *gotta/gotra* can indicate descent affiliation; *nāti* marks kin; other terms identify sons, daughters, mothers, fathers, siblings, wives, husbands, masters and dependants. Such vocabulary is evidence that kinship mattered, not a ready-made ethnographic diagram. Texts composed and transmitted in different communities use the same term with different emphases. The historian must therefore reconstruct relationships passage by passage rather than build one universal “ancient Mithila kinship system” from dictionary equivalents.

Figure 25 — Social scales must not be collapsed into one another

Figure 25 — Social scales must not be collapsed into one another. Household, kin network, lineage and polity overlap but answer different historical questions.

7.10 Lineage politics did not make every household politically equal

The Vajjian and Licchavi political order is often described through lineage or clan language. That vocabulary can illuminate the social basis of assemblies, but it should not be converted into an image of all households enjoying equal political voice. Political lineages may have contained differences of wealth, age, gender and status, while labouring dependants and non-member residents could live within the same

territory. Thapar's discussion of lineage society and the transition to state systems is useful precisely because it treats lineage as a form of political organisation embedded in changing economic relations, not as an undifferentiated family writ large (Thapar 1999).

7.11 Respect for Vajjian elders reveals institutionalised seniority

The “conditions of non-decline” preserved in the Mahāparinibbāna Sutta and the Aṅguttara Nikāya state that the Vajjis should honour and heed their elders (Dīgha Nikāya 16; Aṅguttara Nikāya 7.21). This is valuable evidence for the political importance of seniority and inherited authority. It does not prove a specific domestic residence pattern, but it shows that age and accumulated standing were normative political resources. Household authority and assembly authority may have reinforced one another for elite men, yet the text itself concerns public order rather than the internal organisation of every family.

7.12 The Vajjian rule concerning women and girls is a political norm, not a census of practice

The same list of Vajjian conditions warns against forcibly abducting women or girls of the clans and compelling them to live with abductors (Dīgha Nikāya 16.1.4; Aṅguttara Nikāya 7.21). The passage is important because it makes control over marriage, sexual violence and household incorporation a matter of collective political stability. It suggests that violations against women could provoke conflict between kin groups. But a rule against coercion is not proof that coercion never occurred, nor does it establish women's equality in inheritance, assembly participation or household decision-making. Normative protection and actual autonomy must be studied separately.

7.13 Marriage joined households and kin networks, but practice was diverse

Marriage transferred people, labour, property claims and ritual obligations between households. Yet the evidence for early historic north Bihar and Anga is not sufficient to reconstruct one uniform marriage rule. Buddhist narratives show arranged marriages, household conflict, remarriage and renunciation; Brahmanical texts classify approved and disapproved unions; later legal traditions elaborate inheritance and marital duties. These materials reveal debate and diversity more clearly than uniform practice. Modern north Indian marriage rules, including present-day caste endogamy and detailed genealogical prohibitions, must not be projected unchanged into the early historic period.

7.14 Dharmasūtras are normative archives, not household surveys

The surviving Dharmasūtras discuss education, marriage, property, inheritance, ritual obligations, sexual conduct, professions and relations among social categories (Olivelle 1999). Their importance is substantial, but so are their limits. They represent Brahmanical expert traditions, often articulate male elite ideals, and disagree with one another. They can show what some normative authors wanted ordered households to look like; they cannot demonstrate that every household in Vaishali, Champa, Mithila or the Nepal Tarai followed those prescriptions. In this volume they are therefore used comparatively and explicitly labelled normative.

7.15 Inheritance rules reveal competition over property and descent

Rules concerning sons, daughters, close kin, teachers, students and royal claims to heirless property demonstrate that inheritance was a contested legal and ritual problem. Āpastamba, for example, discusses succession in the absence of sons and allows a daughter a role within one such sequence, while other texts formulate different priorities (Olivelle 1999). The historical lesson is not that one rule governed all eastern

India, but that property transmission required social recognition. Household history must therefore consider death, succession and the reorganisation of labour as moments when kinship became economically consequential.

7.16 Ambapālī demonstrates female control of substantial resources in a specific elite case

In the Mahāparinibbāna Sutta, Ambapālī of Vesālī travels with carriages, hosts the Buddha and the monastic community, rejects a large offer from Licchavi youths for the privilege of providing the meal, and subsequently donates her mango grove to the Saṅgha (Dīgha Nikāya 16). Whatever the literary shaping of the episode, the narrative imagines a woman publicly controlling valuable movable and landed resources and acting as an independent donor. This is strong evidence against treating all women as economically invisible, but Ambapālī was exceptional in wealth and profession; her autonomy should not be generalised to all women of Vajji.

7.17 Female agency and patriarchal constraint coexisted

Gender history is distorted when it asks only whether women had “high” or “low” status. Early Indian sources preserve women as donors, workers, household managers, renouncers, wives, daughters, mothers, servants and courtesans, while also recording male control over marriage, sexuality, inheritance and public authority. Roy’s work on gender in early India is particularly useful because it treats power as relational and institution-specific rather than assigning one status score to all women (Roy 2010). A wealthy donor, a married cultivator, a servant and a nun occupied very different positions even within the same broad region.

7.18 Mahāpajāpatī Gotamī makes the household–renunciation boundary visible

The Vinaya tradition concerning Mahāpajāpatī Gotamī narrates women seeking “going forth from home into homelessness” and the eventual formation of a bhikkhunī community (Vinaya Piṭaka, Cūlavagga X; Horner 1952). The story is not a neutral transcript of one event; it is part of a monastic legal tradition concerned with rules and institutional legitimacy. Yet its language makes an important social distinction visible: religious renunciation required leaving household obligations and creating a new corporate community. The fact that such departure had to be regulated demonstrates how central the household remained as the ordinary unit from which renouncers exited.

7.19 Renunciation reorganised kinship rather than abolishing it

Monks and nuns depended on lay households for food, cloth, medicines, dwellings and land donations. Lay kin could remain emotionally or materially connected to renouncers, and household members could become donors to institutions in which relatives lived. The monastic world therefore did not stand outside the economy of family life. It redirected resources and created alternative communities with their own seniority, property rules and disciplinary structures. Urbanisation, household accumulation and renunciation were historically connected processes, not mutually exclusive social worlds (Chakravarti 1987; Olivelle 2019).

Figure 26 — Household and renunciation as connected social institutions**Renunciation did not erase the household; it reorganised obligations and flows.**

Figure 26 — Household and renunciation as connected social institutions. Material support, mobility, teaching and continuing kin relations linked lay and monastic worlds.

7.20 Children belonged to economies of learning and labour

Children appear unevenly in elite texts because legal, ritual and religious sources are more interested in succession, education, marriageability or renunciation than in ordinary childhood. Yet households required children to acquire language, agricultural knowledge, craft skills, ritual competence and social roles. Some boys entered formal student relationships in Brahmanical settings; Buddhist and Jain traditions also preserve novices and young renouncers. Girls' training is less visible in many normative sources, a textual silence that should not be mistaken for absence of learning. Household transmission was broader than formal schooling and included work learned by participation.

7.21 Age structured authority, dependency and care

The public honour accorded Vajjian elders suggests that age could be converted into authority, but ageing also produced dependency. Injury, illness and reduced mobility shifted labour burdens within households. Older people transmitted memory, ritual knowledge, property claims and social connections; younger adults supplied much of the physically demanding work. Because ancient sources celebrate venerable elders more readily than frail dependants, household care must often be inferred from demographic necessity rather than narrative prominence.

7.22 Dependants, servants and enslaved labour complicate the image of the kin household

Pāli texts refer to *dāsa* and *kammakāra* categories, while other early Indian sources describe servants, hired workers and forms of unfree labour. Chakravarti situates such labour within the economic world that also produced wealthy *gahapatis* and urban donors (Chakravarti 1987). A household could therefore contain people who were not kin but whose labour sustained domestic production and status. Archaeology generally cannot distinguish a servant's sleeping space from that of a poorer relative. The term "family household" should consequently not erase inequalities of freedom, property or coercion among co-residents.

7.23 Wealthy merchant and landholding households linked domestic life to markets

Setthi and gahapati figures in Buddhist literature are repeatedly associated with substantial wealth, gifts and urban or agrarian resources. Such households could convert surplus into religious patronage, credit, trade and political influence. Their prominence in texts is partly a source bias: monasteries remembered major donors more readily than poor cultivators. Nevertheless, they demonstrate that household accumulation was one mechanism through which the expanding market economy of the second urbanisation entered social life. Property was held, transmitted, consumed and displayed through households even when commercial transactions extended far beyond them.

7.24 Champa shows durable domestic investment but not a recoverable pedigree

Excavations at Champa exposed brick structures, floors, ring-wells and other features belonging to early historic occupation phases (Archaeological Survey of India 1970–76). These remains support a history of dense settlement, water management and durable residential investment in Anga. They may indicate households with sufficient resources to build and rebuild substantial spaces. But no excavated wall can tell us the caste, gotra or exact genealogical composition of its residents without independent evidence. The correct inference is social-economic differentiation, not a named family structure.

7.25 Chirand reminds us that household change was not only urban

Chirand's long occupational sequence shows household economies adapting through major technological and exchange transformations. By the early historic phase the settlement participated in iron-using and NBPW networks while retaining a strong riverine and agrarian base (Archaeological Survey of India 1962–63; Verma 1971). Families and co-residential groups in such places experienced urbanisation indirectly through markets, tools, prestige goods and institutional demands. A history restricted to palaces and walled cities would therefore miss much of the household transformation occurring in villages and riverine settlements.

7.26 Anga must not be reconstructed only from Magadhan or Vajjian texts

Champa is well represented archaeologically, but household narratives explicitly located in Anga are less abundant than the wider Buddhist textual record for Magadha and Vesālī. This asymmetry requires restraint. Regional social history can use the shared Middle Ganga economic context and Champa's excavated domestic infrastructure, while clearly marking when textual examples come from elsewhere. The existence of comparable pottery, coinage or urban forms does not prove identical marriage, inheritance or kinship rules across every polity.

7.27 Nepal-side Mithila remains an evidentiary frontier for early household history

The cultural geography of Mithila crosses the modern India–Nepal border, but household archaeology for the early historic Nepal Tarai is unevenly published and cannot simply be filled with evidence from Vaishali or Champa. Later Janakpur traditions are historically important, yet they cannot substitute for excavated domestic contexts of the mid-first millennium BCE. The responsible conclusion is therefore asymmetrical: we can discuss regional interaction and later cultural continuity while acknowledging that

early household structures north of the present border remain insufficiently documented for detailed reconstruction.

7.28 “Joint family” and “nuclear family” are poor default categories

Modern demographic categories can be useful when applied to modern censuses, but they are risky when imposed on early historic evidence. A household may expand when sons marry, contract after inheritance, include widowed relatives, servants or apprentices, and change again through migration or death. Even if a residence contained three generations at one moment, that does not prove a permanent joint-family institution. Conversely, a small house need not contain only parents and children. The life-cycle household is a better model: composition changed over time in response to marriage, property, work, mortality and mobility.

7.29 Later caste and genealogical systems must not be projected backward

The early historic sources certainly record social hierarchy, varṇa discourse, occupations, high and low kulas, and politically important lineages. They do not justify importing the fully developed caste subdivisions, Panji structures or Śrōtriya classification of much later Mithila into the Vajjian age. The same source-control principle used throughout this project applies here: a category must be demonstrated for the period in which it is used. Continuity of a regional name or later genealogy is not sufficient evidence for an unchanged household or caste institution.

7.30 Conclusion: the household connected economy, kinship and power

Early historic households were places where food was produced and consumed, children were raised, property transmitted, labour organised, dependants supported or controlled, marriages negotiated, religious gifts prepared and status reproduced. Yet households were not self-contained. They were embedded in kin networks, political lineages, markets, villages, cities and renunciant institutions. Vajji’s public norms concerning elders and women, Ambapālī’s economic agency, the bhikkhunī tradition, the prominence of gahapatis and the domestic archaeology of sites such as Champa together reveal a society in which household relations were fundamental but diverse. Chapter 8 therefore turns from the household to the wider problem of social differentiation before fixed caste narratives are imposed on the evidence.

Figure 27 — The household as a node in the early historic social economy

The household was simultaneously an economic, social, reproductive and ritual institution.

Figure 27 — The household as a node in the early historic social economy. Food, care, property, ritual, labour and exchange were interdependent rather than separate spheres.

Table 7.1 — Household evidence and limits of inference

Evidence	Can support	Cannot establish by itself	Use in this chapter
House plans, floors, hearths, storage	co-residence, repeated domestic activity, investment	exact genealogy, caste, nuclear/joint family form	Champa and comparative Middle Ganga domestic archaeology
Food, tools and craft debris	household production, consumption, labour routines	sex or kinship identity of each worker	linking household economy to Chapters 4–6
Dīgha Nikāya / Aṅguttara Nikāya	Vajjian public norms concerning elders, women, shrines and assemblies	universal compliance or complete family law	source-controlled evidence for Vajji
Ambapālī narrative	textual representation of a wealthy woman controlling resources and donating land	typical property rights of all women	case study of differentiated female agency
Vinaya bhikkhunī tradition	institutional memory of women leaving household life for renunciation	a neutral transcript of one event or all women's experience	household–renunciation interface
Dharmasūtras	Brahmanical normative debates on marriage, inheritance and household duties	actual practice in every Mithila, Vajji or Anga household	comparative normative evidence only
Terms such as kula / gahapati	categories of descent, status and household headship in specific texts	one timeless regional kinship system	terminological caution

CHAPTER 8 — SOCIAL DIFFERENTIATION BEFORE FIXED CASTE NARRATIVES

8.1 Scope: differentiation is not the same as a finished caste system

Early historic society in the Middle Ganga valley was unequal, but inequality should not be reconstructed by placing every person into a later, fully elaborated caste order. Political rank, control of land and labour, ritual prestige, occupation, lineage, gender, wealth, freedom or dependency, and access to institutions could all shape social position. These axes overlapped, yet they did not always coincide. A wealthy merchant might possess substantial economic power without belonging to a ruling lineage; a ritual specialist could claim high prestige without controlling the largest productive resources; an artisan could be indispensable to urban life while occupying a lower social rank in some textual classifications. The task is therefore to reconstruct historically visible forms of differentiation before assuming the later fixity of endogamous jātis. This follows the broader methodological shift from treating caste as a timeless fourfold structure to examining how social formations changed with settlement, production, state formation and ideology (Thapar 1999; Chakravarti 1987; Sharma 1983).

8.2 The sources speak in different social vocabularies

No single source provides a complete social census. Brahmanical normative texts organise society through varṇa and rules of ritual eligibility, marriage, inheritance and conduct. Early Buddhist texts frequently identify people instead through terms such as khattiya, brāhmaṇa, gahapati, seṭṭhi, vāṇijja, occupational labels, and categories of dependence such as dāsa and kammakāra. Archaeology reveals differences in house size, access to imported or prestige goods, craft production and consumption, but it rarely supplies the names by which people classified themselves. Later inscriptions make some occupational and donor categories more visible, yet they post-date much of the period considered here. These vocabularies must therefore be compared rather than collapsed. Apparent disagreement between texts may record different institutions, audiences and purposes rather than a simple choice between a “true” and a “false” social order (Fick 1920; Chakravarti 1987; Aktor 2017).

8.3 Social position worked through several overlapping axes

The most useful model is multidimensional. Birth and lineage mattered in ruling groups and ritual claims. Property and control over productive resources mattered for substantial householders. Occupation mattered because people could be identified as traders, cattle-keepers, metalworkers, potters, barbers or other specialists. Political rank mattered because participation in a gana-sangha assembly was not open to every resident. Dependency mattered because servants, hired workers and enslaved persons did not command the same autonomy as household heads. Gender and age structured access to property, ritual, movement and authority. These axes could reinforce one another, but they could also diverge. Figure 28 therefore treats hierarchy as a field of intersecting relations rather than a single ladder.

Figure 28 — Social differentiation before fixed caste narratives: several overlapping axes

Figure 28 — Social differentiation before fixed caste narratives: several overlapping axes. No single axis explains all early historic hierarchy.

8.4 Varṇa was a powerful classificatory ideal, not a demographic spreadsheet

The fourfold varṇa scheme—Brāhmaṇa, Kṣatriya, Vaiśya and Śūdra—became one of the most influential Brahmanical ways of imagining social order. Dharma literature attached consequences to these categories in ritual entitlement, marriage, work, punishment and social interaction. Yet modern scholarship stresses that the scheme was normative and ideological; other kinds of evidence do not simply reproduce it as a complete description of lived society (Aktor 2017). This distinction is especially important for north-eastern India in the age of the mahājanapadas. A textual rule assigning an occupation to a varṇa does not prove that every historical practitioner of that occupation belonged to one empirically identifiable group, nor does it establish that the same ranking operated uniformly in Vaishali, Champa, rural settlements and frontier zones.

8.5 Buddhist social vocabulary does not map neatly onto the four varṇas

Uma Chakravarti’s analysis of early Buddhist literature, building critically on Richard Fick, emphasises that the categories most visible in Pāli social description do not line up neatly with the full Brahmanical fourfold scheme. Brāhmaṇas and khattiyas are conspicuous, but economic life is often described through categories such as gahapati, seṭṭhi, merchant, cattle-keeper and named crafts rather than through an empirical “Vaiśya” bloc. Likewise, labouring dependence is frequently expressed through dāsa and kammakāra rather than by making “Śūdra” the ordinary descriptive term for all service work (Fick 1920; Chakravarti 1987). This does not mean that varṇa ideas were absent; it means that social practice generated additional categories that a historian must take seriously on their own terms.

8.6 The gap between normative and empirical categories is historical evidence

The mismatch between classificatory schemes is itself informative. It shows a society in which expanding agriculture, cities, merchant wealth, specialised crafts, political oligarchies and renunciant institutions created forms of status that could not be described adequately through one inherited ideological vocabulary. The historian should therefore resist translating gahapati as “Vaiśya,” khattiya as a simple equivalent of every later

Kṣatriya caste, or dāsa-kammakāra as a synonym for Śūdra. Figure 29 visualises this non-equivalence. Categories could intersect, and later traditions could assimilate them more closely, but the early historic evidence must be allowed to retain its plurality.

Figure 29 — Normative varṇa scheme and empirical social categories in early Pāli sources. The relationship is not one-to-one.

8.7 Brāhmaṇa status joined ritual authority to social competition

Brāhmaṇas appear in Buddhist as well as Brahmanical sources, which indicates that the category had social visibility beyond texts written by Brahmanical specialists. Yet the sources also preserve arguments about what made a true brāhmaṇa: birth, learning, conduct, sacrifice, austerity or ethical achievement. Such debate implies that status was claimed and contested, not merely recorded. In the expanding eastern polities, ritual specialists interacted with rulers, householders and renunciants in an environment where new forms of wealth and political authority were developing. Their prestige could be substantial, but it was not identical to political sovereignty or mercantile wealth. The presence of contest over the meaning of brāhmaṇa status should therefore be treated as evidence of social negotiation rather than as proof that a single uncontested hierarchy governed every community.

8.8 Khattiya status was especially important in ruling lineages and gana-sanghas

Pāli sources use khattiya prominently for ruling and aristocratic groups. In gana-sangha contexts such as the Licchavis and other oligarchic lineages of the north-east, khattiya identity was closely tied to political privilege and descent. This makes it dangerous to translate republican or assembly government into social democracy. A polity could distribute authority among multiple elite lineages while excluding most residents from the decisive political body. Thapar's distinction between lineage systems and state formations is useful here: collective rule among chiefs or lineage heads is still compatible with sharp internal hierarchy (Thapar 1999). The political significance of khattiya status also helps explain why social rank cannot be reduced to ritual ranking alone.

8.9 Gahapati marked substantial household status in agrarian and urban society

The gahapati is one of the most important categories that disappears when early society is forced into a four-varṇa template. In early Buddhist literature the term often denotes a substantial lay household head associated with property, agriculture, wealth, productive resources and local standing. Gahapatis could support renunciants, employ labour and participate in market and agrarian networks. Chakravarti therefore treats the category as central to the new social economy of the Middle Ganga valley (Chakravarti 1987). Not every gahapati was a merchant, and not every householder was a gahapati of comparable means. The term points to a social location produced by household control of resources; it should not be mechanically converted into a later caste name.

8.10 Setṭhi wealth created another axis of urban prestige

The setṭhi or wealthy merchant-financier represents a form of prominence associated with commerce, capital, credit and urban institutions. Literary traditions about major donors illustrate how mercantile wealth could produce public influence without being identical to royal or ritual authority. Older scholarship sometimes attempted to fit such people directly into the Vaiśya category, but the texts often identify them by economic title instead. This distinction matters for Champa and other commercial centres discussed later in the volume. Urbanisation created social power through circulation and accumulation as well as through land and lineage. Wealth could support monasteries, public works and networks of dependants, giving economic elites a visibility that a purely varṇa-based reconstruction would understate (Fick 1920; Chakravarti 1987).

8.11 Occupation was a practical language of social identity

Early Buddhist narratives identify people as traders, cattle-keepers, potters, metalworkers, barbers and other specialists. Such labels show that occupation could function as a meaningful social identity, especially for groups outside ruling and ritual elites. This does not mean that every occupation was already a closed hereditary caste. A profession could be learned within families, organised through local networks and associated with status without yet possessing all the later features of a jati. Fick's early twentieth-century study already noted the complexity of north-eastern society, and Chakravarti's later work emphasised the empirical importance of occupational categories in the Pāli record (Fick 1920; Chakravarti 1987). The safest historical language is therefore "occupational group" unless the evidence demonstrates heredity, endogamy and durable corporate boundaries.

8.12 Skilled crafts could be economically essential and socially unequal

Metalworking, pottery, carpentry, textile production, ivory working, leather work and other crafts were indispensable to early urbanisation. Archaeological concentrations of specialised production show increasing division of labour, while texts supply names for some occupational specialists. Economic necessity, however, did not guarantee equal prestige. Work involving particular materials, bodily substances or service relations could carry different valuations in different textual traditions. At the same time, skilled production created expertise and bargaining power. The relationship between occupation and rank was therefore neither uniformly degrading nor uniformly empowering. Chapter 11 examines craft organisation in detail; here the key point is that occupational differentiation preceded and contributed to later social boundary-making without allowing us to identify every early craft group with a later caste bearing a similar occupation.

8.13 Dāsa and kammakāra reveal relations of dependence and coercion

The presence of dāsa and kammakāra in early sources demonstrates that some households and institutions depended on labour performed by people with less autonomy than substantial household heads. The terms cover forms of servitude, slavery, hired labour and dependent work whose exact legal conditions varied by text and period. It would be misleading either to erase coercion by translating every dāsa as a generic “servant” or to assume that all such persons occupied one uniform form of chattel slavery. Sharma’s work on lower orders and Chakravarti’s social history both insist on relating status to labour and control over resources rather than discussing ritual rank in isolation (Sharma 1990; Chakravarti 2007). These categories make inequality visible from below.

8.14 Labour status could cut across later varṇa expectations

A key methodological consequence follows from the prominence of dāsa-kammakāra and occupational workers: economic dependence did not need to be expressed through the same categories as Brahmanical ritual classification. A person could be socially subordinate because of labour relations, debt, household dependency or lack of property even when the text did not label that person a Śūdra. Conversely, the abstract assignment of service to Śūdras in normative literature does not identify the status of every worker in the archaeological or Buddhist record. This separation between economic relation and ritual category is crucial for writing a socio-economic history that does not substitute prescription for observation (Sharma 1983; Aktor 2017).

8.15 Gana-sangha government was oligarchic rather than socially egalitarian

Vaishali’s association with the Vajjian confederacy can encourage anachronistic descriptions of a “republic” as if all inhabitants enjoyed equal citizenship. The surviving traditions instead point to assemblies of politically entitled lineages and chiefs. The famous Vajjian conditions in the Mahāparinibbāna Sutta concern collective meetings, established institutions, elders, women, shrines and arahants; they describe norms of political cohesion, not universal suffrage (Walshe 1995). Mishra’s reconstruction of the Vajjian constitution remains historiographically important but uses modern constitutional analogies that must be handled cautiously (Mishra 1962). Figure 30 therefore presents political participation as one axis of hierarchy: collective rule among elites could coexist with household wealth differences, occupational stratification and dependent labour.

Political participation was not the same as social equality

Figure 30 — Differentiated participation in a gana-sangha polity. Collective rule among entitled lineages did not imply universal social equality.

8.16 Lineage rank and economic wealth were related but not identical

Ruling descent could confer access to office and assembly participation, while mercantile or agrarian wealth could create substantial influence outside the political lineage core. A wealthy gahapati or seṭṭhi might command more movable resources than a poorer member of an aristocratic lineage, yet the latter could possess privileges of birth and political participation unavailable to the former. This is exactly why a single hierarchy is insufficient. Early state formation brought several ranking systems into contact: descent, ritual status, control of labour, market wealth and office. Their interaction created opportunities for competition, patronage and alliance, but not necessarily a unified scale on which every person could be placed.

8.17 Gender structured every social category without producing one uniform female status

Women were differentiated by family status, wealth, marital position, age, occupation, enslavement or dependency, and access to religious institutions. Elite women could control resources in exceptional cases; poorer women performed agricultural, domestic, craft and service labour that is much less visible in elite texts. Normative restrictions on marriage, inheritance and sexuality therefore need to be read alongside evidence for female donors, courtesans, nuns and household managers. Gender was not a separate hierarchy added after caste or class; it intersected with them. The same label of high family status could produce different opportunities for men and women, while renunciation could create new forms of female authority within continuing institutional constraints (Collett 2016; Chakravarti 2007).

8.18 Ambapālī shows why social categories must be read case by case

Traditions about Ambapālī of Vesālī portray a woman of wealth, public visibility and control over property who interacts directly with the Buddha and the Licchavis. Her case cannot be made representative

of all women, nor should later labels about courtesans be used to assign her a simple place in a caste ladder. Instead, the narrative demonstrates that urban societies could recognise forms of female economic agency that intersected with sexuality, patronage, civic prestige and elite competition. The example is valuable precisely because it resists a flat model: gender constraint coexisted with forms of wealth and public authority. Chapter 9 examines women in greater detail.

8.19 Renunciation challenged some status claims without abolishing social hierarchy

Early Buddhist doctrine repeatedly questions the idea that spiritual worth is guaranteed by birth. Admission to the saṅgha could create a new institutional identity in which seniority by ordination and discipline mattered. Stories such as that of Upāli, traditionally remembered as a barber connected with the Sakyan princes, dramatise a reversal of worldly precedence when elite men are asked to honour someone ordained before them. Such narratives are powerful critiques of inherited status, but they should not be turned into evidence that caste or class disappeared in Buddhist communities. Monasteries depended on lay economies, retained gendered rules, and operated within societies structured by wealth, family and political power. The evidence therefore shows ideological challenge and institutional re-ranking, not an instant egalitarian social revolution (Chakravarti 1987; Horner 1952).

8.20 Ethical universalism and social practice could coexist in tension

Buddhist texts can relativise birth status by making conduct and insight central to moral and spiritual evaluation. At the same time, the same textual world recognises khattiyas, brāhmaṇas, high and low families, wealthy householders, servants and occupational groups. The coexistence of these registers is historically important. Religious critique did not require authors to deny the social classifications around them; rather, it could redirect the criterion of ultimate worth. Historians should therefore avoid two opposite errors: treating Buddhism as simply reproducing Brahmanical hierarchy, or describing it as having abolished social distinction in practice. The tension between ethical universality and inherited social relations is itself part of the history of early north-eastern India.

8.21 Kula and jāti cannot simply be translated as modern caste

Words translated as “family,” “birth,” “kind,” “lineage” or “caste” changed meaning across genres and centuries. Kula may refer to family or lineage status; jāti can indicate birth or a social category without necessarily denoting a fully formed modern-style endogamous caste. Thapar’s discussion of social terminology during the transition from lineage to state warns against assuming that later meanings were already fixed in the mid-first millennium BCE (Thapar 1999). The safest method is contextual: ask what a term does in a particular passage—does it rank families, regulate marriage, identify occupation, distinguish political descent, or make a doctrinal argument? Translation should follow that function rather than importing the whole later institution into a single ancient word.

8.22 Marginalised labels do not justify back-projecting later untouchability unchanged

Early texts contain labels for people represented as low, impure, despised or socially distant, including caṇḍāla and pukkusa/pukkasa in some traditions. Such evidence is important for the history of exclusion, but it does not by itself prove that the full later institution of untouchability, with all its regional practices and hereditary boundaries, already existed in an identical form. Sharma’s *longue-durée* study of lower orders

demonstrates that social degradation developed through changing ritual, occupational and economic relations over centuries (Sharma 1990). A historically controlled account should record early stigma and exclusion where the sources attest them while refusing to convert resemblance into timeless continuity.

8.23 Hunters, fishers and forest-linked workers complicate agrarian models

Not everyone fitted neatly into an agrarian village or urban craft economy. Texts refer to hunters, fishers and other people whose livelihoods depended on rivers, wetlands, forests and animal resources. Archaeology from the region likewise demonstrates the continuing importance of fish, turtle, molluscs and wild resources discussed in Chapters 3 and 4. Such livelihoods could be economically essential while being represented ambivalently or negatively in some normative traditions. Their presence reminds us that social differentiation also followed ecological niches. Later caste histories sometimes attach particular communities permanently to such occupations, but early evidence should be described at the level it supports: livelihood, occupational naming and social valuation, not assumed unbroken community identity.

8.24 Urban neighbourhoods cannot be labelled by caste from artefacts alone

Archaeological differences within a town—house size, craft debris, luxury goods, drains, wells, streets and waste—can reveal unequal access to resources and specialised activity zones. They cannot normally identify the caste of residents. A quarter containing metalworking debris is evidence for concentrated production, not automatically a “smith caste quarter.” A large residence suggests investment and resources, not a specific varṇa. This caution is essential at sites such as Champa and Vaishali where literary memory is rich enough to tempt retrospective identification. Material inequality and social classification must be connected only where independent evidence allows it (Allchin 1995; Chakrabarti 2009).

8.25 Consumption differences reveal inequality more securely than named status

Variation in fine wares, ornaments, beads, imported materials, storage capacity and residential investment can indicate unequal consumption or access. Yet archaeological wealth is not a direct translation of legal or ritual rank. A prosperous merchant household could possess more expensive objects than a ritual specialist; goods could be gifts, heirlooms, trade stock or institutional property. The strongest archaeological claim is therefore comparative: some households or areas had greater access to resources than others. Linking that inequality to a named social category requires textual, inscriptional or spatial corroboration. This evidentiary discipline prevents artefacts from being used to “prove” a caste hierarchy they cannot name.

8.26 Social mobility existed, but it should not be romanticised

Economic expansion could create new wealth through agriculture, trade and specialised production. Renunciation could confer new religious status. Service at court or participation in political institutions could alter a household’s position. Such possibilities show that social order was not completely frozen. Yet mobility was constrained by birth, lineage privilege, gender, dependency and inherited resources. Stories of individuals who cross status boundaries are therefore evidence that boundaries mattered, not proof that they were irrelevant. A historical account should recognise both movement and constraint, avoiding the twin myths of an entirely fluid society and an already immobile caste system.

8.27 Anga and Champa require local evidence rather than borrowed social templates

Champa's role as an urban and commercial centre makes it plausible that merchants, artisans, labourers, householders and political authorities interacted there in complex ways. Archaeology supports urban investment and craft activity, while Buddhist and Jain traditions place Anga within wider networks of the eastern Ganga valley. What is much harder to recover is the exact local ranking of named social groups. It would be methodologically weak to take a hierarchy reconstructed for Magadha or Kosala and simply relabel it "Anga." Chapter 14 returns to Champa with a stronger economic focus. For the present chapter, Anga demonstrates the need to distinguish region-wide processes from locally proven institutions.

8.28 Nepal-side Mithila is especially vulnerable to retrospective classification

For the early historic Tarai and Nepal-side Mithila, archaeological and textual evidence remains uneven. Later social formations, landholding structures and caste labels are much better documented, but they cannot be carried backward across a millennium or more. Shared religious traditions and cross-border mobility do not prove that every later community category existed with the same name and boundary in the early historic period. This volume therefore treats the Nepal Tarai as part of an interaction zone while keeping the evidentiary frontier visible. Where the data are insufficient, absence of reconstruction is preferable to invented continuity.

8.29 Later caste formations must be studied as historical outcomes

More durable caste formations could emerge through the long interaction of occupational specialisation, hereditary transmission of work, marriage boundaries, ritual ranking, political incorporation, control of land and service obligations. But these processes operated unevenly across regions and centuries. Figure 31 therefore represents caste formation as a possible long-term stabilisation of several social boundaries rather than as a system that appeared fully formed at one date. This approach also prevents later Maithil genealogical, Panji, Śrotriya or other historically documented classifications from being projected into the age of the Vajji confederacy. The later evidence is important precisely because it has its own history.

From social differentiation to later caste formations: a process, not an instant system

Figure 31 — Long-term pathways that may stabilise social boundaries. This is not a date for a single 'moment of caste formation' and must not project later jātis into the sixth-fifth centuries BCE.

Figure 31 — From social differentiation to later caste formations: a long-term process rather than an instant or uniform system.

8.30 Conclusion: early historic hierarchy was plural, contested and changing

The strongest conclusion is not that early Mithila, Vajji and Anga were “casteless,” nor that they already possessed the complete social architecture familiar from much later periods. The evidence shows stratification through lineage, ritual status, wealth, occupation, political privilege, gender and dependency. Brahmanical varṇa theory was historically influential, but Pāli texts reveal additional empirical categories created by agrarian expansion, urbanisation, trade and household production. Gana-sangha politics could be collective yet oligarchic; Buddhist ethics could challenge birth privilege without dissolving social inequality; occupational groups could be durable without being demonstrably identical to later jātis. Social differentiation should therefore be written as a process. The next chapter turns specifically to women, whose experiences expose particularly clearly how status, labour, family and institutional power intersected.

Table 8.1 — Social categories, evidence and limits of inference

Category / evidence	What it can support	What it cannot establish by itself	Use in this chapter
Varṇa terminology	normative ranking, ritual and legal ideals	complete demographic structure of a settlement	used as ideological classification, not census
Khattiya / ruling lineage	political descent and elite participation in some polities	universal equality within gana-sanghas	used to separate oligarchic participation from citizenship
Gahapati / setṭhi	property, household standing, mercantile or urban wealth	automatic identification as Vaiśya caste	used to reconstruct economic status outside a fourfold template
Occupational labels	work, skill, practical	fully hereditary or	used for artisans,

Category / evidence	What it can support	What it cannot establish by itself	Use in this chapter
	social identification	endogamous jātis	traders, fishers and other specialists
Dāsa / kammakāra	dependence, labour subordination, possible coercion	one uniform legal form of slavery	used to recover labour hierarchy from below
House size and material wealth	unequal access to resources and consumption	named caste, varṇa or genealogy	used only as archaeological evidence of inequality
Later caste/genealogical records	later social boundaries and historical memory	unchanged early historic identity	reserved for later chapters and never retrojected

CHAPTER 9 — WOMEN IN EARLY MITHILA–VAJJI–ANGA

Women in the early historic societies of Mithila, Vajji and Anga cannot be reconstructed as a single, uniform social category. The surviving evidence is uneven and genre-bound: archaeology reveals households, production, consumption and inequality but seldom identifies gender securely; Buddhist and Jain texts preserve named women and institutional debates but are literary and religious compositions; Brahmanical normative texts prescribe marriage, inheritance and conduct rather than recording every local practice. This chapter therefore asks a narrower historical question: what forms of work, dependence, patronage, kinship, public presence and renunciation can be supported by the evidence, and where must inference stop?

9.1 Scope: women were differentiated by more than gender

Gender shaped access to property, labour, marriage, ritual and public institutions, but it did not erase differences of wealth, age, household position, occupation, dependency or lineage rank. An elite woman connected to a ruling family, a prosperous urban patron, a female household manager, a dependent servant, a *gaṇikā*, a lay devotee and a renunciant occupied very different social locations. The safest reconstruction therefore treats “women” as an analytical category that intersects with class, kinship, political status and work rather than as a homogeneous group. This also prevents later ideals of the respectable housewife, later caste-specific marriage rules, or later regional customs from being read backward into the first millennium BCE without evidence (Chakravarti 1987; Thapar 1999).

9.2 The source problem is especially acute for women

Most early sources were produced, transmitted or institutionalised in settings dominated by men. That does not make women invisible, but it affects what is recorded. Normative texts often speak about women when regulating marriage, sexuality, inheritance or household order. Monastic texts speak about women when they become donors, disciples, nuns, relatives of monks, or subjects of disciplinary rules. Narrative texts often select exemplary or exceptional lives. Archaeology usually preserves houses, tools, food residues, ornaments and burials without giving the names or social identities of the people who used them. The result is a record rich in episodes but poor in representative statistics. A responsible social history must therefore distinguish an attested possibility from a typical pattern.

9.3 Regional evidence is uneven: Vesālī is unusually visible

Among the regions considered in this volume, Vesālī/Vaiśālī is unusually prominent in early Buddhist textual memory. The Mahāparinibbāna Sutta places the Buddha repeatedly in the Vajjian country and preserves episodes involving Ambapālī, the Licchavis and rules of Vajjian political conduct. The Vinaya and Aṅguttara traditions also connect Mahāpajāpatī Gotamī with Vesālī. By contrast, the evidence for women specifically in early Anga/Champa and in the wider area later identified with Mithila is thinner and often indirect. This asymmetry must remain visible: better-documented Vesālī can illuminate possibilities within the wider Middle Ganga social world, but it cannot simply stand in for every settlement in Mithila or Anga.

Figure 32 — Evidence windows for reconstructing women's lives in the early historic region. Each source type reveals different aspects and has different limits.

9.4 Household labour is fundamental but archaeologically difficult to gender

Grinding, cooking, water collection, fuel preparation, food storage, textile work, childcare, cleaning and care for the sick were essential to household reproduction. Archaeological evidence for hearths, ovens, grinding stones, storage, spindle whorls, beads and domestic spaces helps reconstruct these activities, but the objects themselves rarely identify the sex of the worker. Textual traditions often associate textile work, food preparation and household management with women, yet those associations should not be turned into an exclusive division of labour without local proof. The strongest inference is therefore that early households depended on intensive reproductive and productive labour, much of which could be gendered in practice, while the precise allocation of tasks varied by household status and circumstance.

9.5 Marriage linked households, property and lineage

Marriage was not merely a private relationship. In agrarian and urban societies it connected families, transferred labour and resources, organised sexuality and reproduction, and could create alliances between lineages. Brahmanical Dharmasūtras preserve competing prescriptions concerning legitimate unions, inheritance and the duties of spouses, but they are prescriptive compositions and cannot be treated as a direct ethnography of Vajji or Anga (Olivelle 1999). Buddhist narratives likewise show marriages, parents, children and affinal relationships but do not provide a single marriage law. The historical conclusion is therefore structural rather than legalistic: marriage was a major institution for organising household continuity, but the forms and rights attached to it were not uniform across all communities.

9.6 Patrilineal ideals did not eliminate women's social leverage

Many normative traditions organise descent and inheritance through male lines and define women relationally as daughters, wives and mothers. Yet relational status could itself carry influence. Marriage could connect politically important families; motherhood could affect succession and household authority; and elite women might occupy significant positions within kin networks even when formal office was male-dominated. Conversely, women without powerful kin or property were more vulnerable to coercion. The

evidence therefore points neither to complete female seclusion nor to generalized equality. It points to social leverage that was often mediated through household, kinship, wealth and reputation, with very different outcomes for women situated differently within the social hierarchy.

9.7 Property rights cannot be reconstructed from one famous case

The evidence for women's control over property is patchy. Later legal categories such as *strīdhana* developed important histories, but they should not be projected wholesale into the early Vajjian period. Narrative evidence can nevertheless show that particular women controlled resources. The Ambapālī episode in DN 16 is especially important because the narrative presents her as controlling a mango grove, arranging transport and a large meal, refusing a lucrative offer from Licchavi youths, and donating the grove to the Buddhist community. This is direct textual evidence for resource control by one prominent woman; it is not a statute defining the property rights of all women in Vesālī.

Figure 33 — Women's social positions were formed across intersecting domains rather than by gender alone.

9.8 Ambapālī's public presence challenges a domestic-only model

Ambapālī appears in the Mahāparinibbāna narrative not as a hidden household figure but as a public actor. She travels in carriages, approaches the Buddha in her own grove, negotiates priority over a meal invitation with Licchavi elites, hosts the Saṅgha and donates property. The episode is literary, but the social world it presupposes includes urban women whose status could be publicly recognised and economically consequential. Ambapālī's profession also complicates simplistic moral categories: the same text that labels her a *gaṇikā* portrays her as wealthy, decisive and capable of major religious patronage (DN 16; Walshe 1995).

9.9 Ambapālī's grove shows how patronage could convert wealth into institutional memory

The donation of Ambapālī's mango grove is historically significant at the level of social mechanism. Resource control allowed a private holder to support a renunciant institution; the gift then transformed a personal estate into a remembered religious site. Buddhist texts subsequently locate teachings in Ambapālī's Grove, showing how patronage could reshape the sacred and institutional geography of a city. The episode

should not be romanticised as proof that women generally enjoyed equal control over landed resources. Its value lies precisely in showing a documented route through which one woman's wealth and public standing became durable institutional patronage.

9.10 The *gaṇikā* belonged to the urban economy, not outside society

Older histories often reduce figures such as Ambapālī to moral anecdotes. A socio-economic reading instead asks what the category of *gaṇikā* implies about the city. Such women were associated in literary sources with trained entertainment, sexuality, elite clientele, ornament, mobility and high-value exchange. Their position could combine wealth and visibility with stigma and vulnerability. That combination is historically revealing: urbanisation generated occupations and public roles that did not fit neatly into the idealised household order. Ambapālī therefore belongs to the history of labour, consumption, gender and urban hierarchy as much as to the history of Buddhism.

AMBAPĀLĪ: WHAT THE VESĀLĪ NARRATIVE SUPPORTS

Supports resource control and public patronage in one prominent case — not a general property law for all women.

Figure 34 — Ambapālī and resource control in the Vesālī narrative: from urban status to durable religious patronage.

9.11 Female lay followers formed part of the Buddhist social constituency

Early Buddhist texts recognise both male and female lay followers. The *Āṅguttara Nikāya* can describe a competent female lay follower as part of the fourfold community alongside monks, nuns and male lay followers (AN 4.7). Other passages address ethical conduct, generosity and household responsibilities specifically to women. These texts are normative and pan-regional rather than local censuses, but they demonstrate that Buddhist institutions imagined women not only as relatives of male devotees but as religious participants in their own right. In a city such as Vesālī, where monastic communities depended on lay support, female participation could therefore operate through gifts, meals, property, ritual attendance and sustained patronage.

9.12 Visākhā is a useful comparator, not evidence for Vesālī

The famous laywoman Visākhā is associated above all with Sāvattthī, not Vesālī. Her prominence as a donor and household manager is nevertheless useful comparatively because early Buddhist literature explicitly discusses a woman's competence in work, management of domestic servants, protection of household wealth, generosity and religious knowledge (AN 8.49). The correct use of this material is

comparative: it shows categories through which some early Buddhist communities conceptualised prosperous female householders. It should not be cited as direct proof that women in Mithila, Vajji or Anga possessed identical rights, duties or household structures.

9.13 Mahāpajāpatī Gotamī links household care, textile production and religious giving

MN 142 presents Mahāpajāpatī Gotamī offering cloth that she had herself spun and woven. The narrative also remembers her as the Buddha's maternal aunt and foster mother. Although the scene is set at Kapilavatthu rather than Vesālī, it is useful because the same figure later appears in the Vesālī ordination tradition. The episode joins several domains often separated in modern analysis: women's household and textile labour, kin-based care, personal religious devotion and institutional giving. It also cautions against treating productive work as merely "domestic": spinning and weaving generated objects of exchange and religious value.

9.14 Vesālī is central to the Buddhist memory of women's ordination

The Pāli Vinaya and AN 8.51 narrate Mahāpajāpatī Gotamī's journey with Sakyan women to Vesālī after an earlier request for women to go forth had been refused. At Vesālī, Ānanda intervenes and the narrative culminates in the establishment of a bhikkhunī order under specified conditions. Comparative scholarship shows that different Buddhist textual traditions preserve related but not identical versions of the foundation story (Collett 2013). For regional history, the crucial point is not to harmonise every detail but to recognise that Vesālī became a major remembered setting for the institutionalisation of female renunciation.

9.15 The foundation story is institutional history and also a contested memory

The ordination narrative should not be read as a stenographic record of one administrative event. Its rules, speeches and chronology were transmitted within monastic institutions that had their own concerns about authority, seniority, sexuality and discipline. Comparative textual studies have demonstrated differences among Pāli, Chinese, Sanskrit and Gāndhārī witnesses (Collett 2013). Yet those differences do not make the tradition historically useless. They show that early Buddhist communities repeatedly had to think about how women could move from household status into an organised renunciant life, and how the resulting female institution related to male monastic authority.

9.16 Renunciation created a socially recognised path outside marriage

Female renunciation was significant because it offered an institutional identity not defined solely by marriage, motherhood or male kin. Nuns could live within a corporate religious community, undertake disciplined training and appear in textual traditions as teachers and accomplished practitioners. This did not remove gender hierarchy. Vinaya traditions impose additional rules and dependencies on nuns, and safety concerns recur in narratives about female mobility. Nevertheless, the existence of an organised female renunciant order widened the range of socially intelligible female lives in the early historic religious landscape (Horner 1952; Collett 2013).

FEMALE RELIGIOUS AND SOCIAL PATHWAYS

Paths expanded social possibilities, but hierarchy, kinship, wealth and vulnerability continued to matter.

Figure 35 — Female religious and social pathways: opportunity and constraint coexisted.

9.17 Institutional subordination and religious competence coexisted

It is misleading to choose between two totalising pictures—either “Buddhism liberated women” or “Buddhism simply reproduced patriarchy.” The evidence supports both institutional constraint and acknowledged female religious competence. Rules could subordinate the nuns’ order to monks, while other texts name accomplished bhikkhunīs, female teachers and wise female disciples. AN 8.53, set near Vesālī, presents Mahāpajāpatī requesting concise teaching for solitary practice; the Buddha responds with criteria for judging authentic Dhamma. The scene assumes a female renunciant capable of independent discipline and doctrinal evaluation even within a gendered institutional order.

9.18 The Therīgāthā preserves women’s religious voices, but transmission must be analysed

The Therīgāthā is exceptional because it preserves verses attributed to early Buddhist women. It should neither be dismissed as fiction nor treated as transparent autobiography. The poems belong to a textual tradition shaped by oral transmission, compilation and later biographical commentary. Modern scholarship therefore distinguishes the verses from much later narrative expansions (Collett 2016). Used carefully, the collection demonstrates that the remembered early Buddhist community included women articulating ageing, grief, desire, renunciation, insight and liberation in the first person. It is evidence for a religious discourse in which women could be represented as subjects of knowledge rather than only objects of regulation.

9.19 Ambapālī’s Therīgāthā verses add another layer, not a simple biography

The Therīgāthā attributes to Ambapālī a sustained meditation on ageing in which former beauty is contrasted with bodily decline (Thig 13.1). This literary voice should not simply be fused with every episode of the DN 16 Ambapālī narrative to create a modern biography. The texts belong to different compositional settings. Read together but not collapsed, they show how the tradition remembered one woman in multiple

registers: urban public figure, donor, later renunciant and poet of impermanence. That multiplicity is historically more valuable than a single harmonised life story because it reveals changing modes of female exemplarity.

9.20 Motherhood and grief appear as social as well as religious experiences

Early Buddhist women's narratives frequently place renunciation against the background of marriage, motherhood, bereavement or domestic distress. Such stories cannot yield statistics about maternal mortality, infant death or widowhood, but they reveal the emotional and social weight attached to kinship. The broader lesson is that religious change did not occur outside family life: renunciation could emerge from experiences embedded in households. Modern analysis should resist turning grief narratives into stereotypes that women were naturally more emotional, just as it should resist reading every renunciation as a modern act of individual emancipation (Collett 2016; Salgado 2013).

9.21 Dependent women remain harder to see than elite patrons

Sources disproportionately preserve women who were exceptional, wealthy, religiously exemplary or connected to powerful households. Female servants, slaves, hired workers and other dependants appear more fragmentarily. This creates a serious archival bias. The presence of *dāsa* and *kammakāra* relations in early sources, discussed in Chapter 8, implies households in which women as well as men could occupy dependent positions. Yet the evidence rarely permits a precise local reconstruction of their numbers, legal status or daily labour. A social history must therefore keep vulnerable and low-status women analytically present even when named biographies are absent.

9.22 Textile and food work connected household labour to the wider economy

Spinning, weaving, food processing and preparation are repeatedly associated with women in normative and narrative sources, while archaeology provides the tools and installations for these activities. The important economic point is that such work was not “non-economic” merely because much of it occurred in households. Cloth, prepared food, stored grain, dairy products and care labour reproduced households and could support markets, gifts and religious institutions. Mahāpajāpati's cloth offering is a particularly clear illustration of productive labour becoming religious wealth. The chapter therefore treats household production as part of the economy rather than as a separate private sphere.

9.23 Women's mobility ranged from constrained to highly public

The sources preserve very different patterns of movement. Ambapālī travels by carriage in the public space around Vesālī; Mahāpajāpati's ordination narrative depicts a difficult journey to Vesālī; nuns' disciplinary rules reveal concern with safe travel and interactions with men; dependent women may have had far less freedom of movement. These differences show why the binary “secluded versus free” is inadequate. Mobility depended on wealth, institution, age, occupation, kin protection and vulnerability. The archaeological landscape of roads, rivers, monasteries and urban markets created opportunities for movement, but social permission and personal security were distributed unequally.

9.24 Vajjian political ethics included a rule concerning women and girls

In DN 16 the Buddha asks whether the Vajjis refrain from coercing and forcing the women and girls of their clans to live with them against their will; continued observance is included among the conditions associated with Vajjian welfare. The passage is important because it places treatment of women within a

discourse about political stability rather than only household morality. But it must be interpreted carefully. A normative prohibition against abduction or coercion does not prove that such acts never occurred. It shows that the tradition represented control over elite or clan women as a politically consequential issue within the Vajjian order (DN 16; Mishra 1962).

9.25 Political kinship could make elite women central to inter-lineage relations

In oligarchic and monarchical settings, marriage among prominent families could affect alliance, succession and conflict. Later Buddhist and Jain narratives contain many genealogical claims concerning Licchavis, Videhans and the family of Mahāvīra. Such genealogies are valuable as political memory but should not be accepted wholesale as contemporary constitutional documentation. What can be stated more securely is that where political authority was organised through ruling lineages, the marriage and protection of women belonging to those lineages could have consequences beyond the household. The Vajjian anti-coercion principle in DN 16 makes best sense within such a world of politically significant kinship.

9.26 Jain traditions preserve important memories of female renunciation

Jainism also developed organised communities of women renunciants. Later Śvetāmbara tradition gives Candanā/Candanabālā a prominent place in stories of Mahāvīra's alms and female discipleship, while later textual and sectarian histories elaborate the roles of nuns in the fourfold Jain community. These traditions are indispensable for the social history of Jain women, but their layers must be dated and separated. A late manuscript image or medieval hagiography cannot be used as direct evidence for a sixth- or fifth-century BCE event. The historically defensible conclusion is that female renunciation became a durable and institutionally important feature of Jain religious life, while the biographies of named early women remain textually mediated (Dundas 2002; Jaini 1991).

9.27 Jain debates show that gender remained a doctrinal and institutional question

Later Digambara and Śvetāmbara disagreements over whether women could attain liberation in a female body demonstrate that gender continued to be debated within Jain traditions. Those disputes are later than Mahāvīra and should not be projected unchanged into his lifetime. Their relevance here is historiographical: they remind us that “Jain views of women” were never a single timeless position. The existence of nuns, laywomen and female exemplars coexisted with debates over body, clothing, authority and salvation. For the early period, the historian should therefore reconstruct institutions and narratives without importing the fully developed positions of later sectarian controversy (Jaini 1991).

9.28 Anga and Champa require a deliberately modest reconstruction

Champa was an important early historic centre, and its urban economy would have depended on women's labour in households, production, service, exchange and reproduction. Yet the surviving evidence does not allow the same named, place-specific reconstruction available for Vesālī. It would therefore be misleading to populate Champa with famous women borrowed from Buddhist stories set elsewhere or to assign later Anga customs to the early city. The chapter uses the broader Middle Ganga evidence to define plausible social processes while marking Anga-specific claims separately. The absence of named women from the surviving record is an archival limitation, not evidence that women were socially unimportant.

9.29 Nepal-side Mithila must not be filled with later custom

For the early historic Tarai and Nepal-side Mithila, archaeological and textual evidence concerning women remains especially uneven. Later Maithil marriage systems, property customs, caste practices and ritual roles are much better documented, but they belong to later historical formations. Their survival in the same broad cultural region does not prove that they existed in identical form in the first millennium BCE. The proper method is to use early archaeology for settlement and material life, early texts for explicitly attested social categories, and later ethnographic or legal evidence only when studying later periods. This protects the Nepal side of the history from retrospective homogenisation.

9.30 Conclusion: agency and constraint must be reconstructed together

The early historic evidence does not support either a timeless picture of female subordination or a celebratory narrative of general emancipation. It reveals women acting within unequal structures as household workers, kin, patrons, public professionals, lay followers and renunciants. Vesālī is particularly important because the same textual landscape preserves political rules concerning women, Ambapālī's conspicuous economic agency and the Buddhist memory of female ordination. These cases demonstrate real possibilities without establishing their universality. The central historical principle is therefore to reconstruct agency and constraint together, always asking which women, in which institution, with what resources, and according to which source.

Table 9.1 — Named women, source settings and limits of inference

Case / category	Source setting	What it supports	What it does not prove
Ambapālī of Vesālī	DN 16; Therīgāthā tradition	Public mobility, substantial resources, patronage, donation of a grove; later renunciant memory	General property law or typical status of all urban women
Mahāpajāpatī Gotamī	Vinaya Kd 20; AN 8.51, 8.53; MN 142	Female renunciation as an institutional problem; textile production and giving; Vesālī as key remembered setting	A single uncontested founding chronology across all Buddhist schools
Vajjian women and girls	DN 16 welfare principles	Normative concern with coercion or abduction as politically consequential	That coercion never occurred, or that all women possessed equal legal autonomy
Visākhā	Āṅguttara Nikāya; Sāvatthī setting	Comparative model of prosperous female household management, generosity and lay participation	Direct evidence for Vesālī, Mithila or Anga
Candanā / Candanabālā	Jain narrative and monastic traditions	Durable Jain memory of female discipleship, almsgiving and renunciation	A fully recoverable contemporary biography or direct evidence for every early Jain woman
Female dependants	Scattered Buddhist/legal references; household	Existence of unequal labour and dependency within	Reliable regional numbers or a complete legal

Case / category	Source setting	What it supports	What it does not prove
	economy	households and institutions	category identical across communities
Women in early Anga / Champa	Indirect regional archaeology and wider textual comparison	Women's necessary participation in household reproduction, labour and urban society	Named local biographies or later Anga customs projected into the early historic period

CHAPTER 10 — AGRICULTURE AND THE RURAL ECONOMY

Agriculture sustained the demographic, urban and institutional transformations discussed in the preceding chapters, but the rural economy cannot be reduced to a single image of the timeless Indian village. In the Middle Ganga plains, cultivation was embedded in floodplain ecology, seasonal rainfall, livestock, household labour, storage, exchange, political extraction and religious patronage. The evidence is uneven. Archaeobotany and excavation can establish crops, food-processing tools and settlement sequences at particular sites; early Buddhist texts illuminate social categories such as gahapati, cultivator and dependent worker; later state and normative texts offer models of land, irrigation and taxation that must not be projected mechanically backward. This chapter therefore reconstructs mechanisms and limits rather than inventing a uniform agrarian system for all of Mithila, Vajji and Anga.

10.1 Scope: the rural economy was historical, not timeless

The phrase “rural economy” covers more than farming. Fields, grazing, livestock, fishing, gathering, fuel, house-building materials, transport, household processing, local exchange and obligations to political or religious institutions all formed part of village and countryside livelihoods. Nor should the village be imagined as an isolated, self-sufficient unit. Chapter 6 showed that early towns depended upon countryside flows of food, fibres, animals and labour, while rural households obtained tools, salt, ornaments and other goods through exchange. The task is therefore to reconstruct a connected agrarian landscape rather than a sealed village economy (Allchin 1995; Sharma 1983).

10.2 Evidence must be matched to the claim

For this region, direct evidence is strongest at excavated sites such as Chirand and at well-studied Middle Ganga comparators such as Senuwar. Archaeobotanical research establishes crop repertoires and long-term diversification, but it does not by itself reveal landownership or tax rates. Pāli literature preserves terms for farmers, cattle-keepers, householders, workers and rulers, yet its narratives are religious compositions rather than agricultural surveys. The Arthaśāstra contains exceptionally detailed agrarian administration, rainfall, irrigation and revenue categories, but its composite date and state-centred perspective make it a comparator for institutional possibilities, not a documentary description of sixth- or fifth-century BCE Vaishali or Champa (Bhattacharya 1978; Olivelle 2013).

10.3 Agrarian intensification had a long prehistory

Early historic agriculture did not begin with the rise of cities. Chapters 2–4 documented long-standing cultivation, animal keeping, fishing and plant processing in the Middle Ganga plains. Chirand and Senuwar show that rice, wheat, barley, pulses and other crops entered diversified farming systems well before the mature early historic horizon. Archaeobotanical synthesis across the Ganga Plain indicates continuity combined with diversification rather than a sudden agricultural invention at the moment of urbanisation (Pokharia et al. 2017). The early historic transformation therefore concerned scale, coordination, surplus, exchange and social differentiation as much as the existence of farming itself.

Figure 36 — Early historic agriculture as a coupled system

Figure 36 — Early historic agriculture as a coupled system: land, water, seed, labour, livestock and storage had to work together.

10.4 Rice was central, but the countryside was not a rice monoculture

Rice was exceptionally well suited to humid and seasonally inundated parts of the eastern Gangetic plain, and it appears prominently in the archaeological record. Yet the same record cautions against reducing the agrarian economy to rice alone. Wheat, barley, pulses and, in wider Ganga Plain sequences, millets, oilseeds and other useful plants demonstrate a more diversified crop repertoire. Different soils, elevations and moisture regimes would have favoured different combinations. A diversified system also spread risk: failure of one crop or season did not necessarily destroy the entire household food base (Pokharia et al. 2017; Singh 2004).

10.5 Two agricultural seasons increased both opportunity and labour demand

The coexistence of monsoon and winter crops at sites such as Chirand and Senuwar implies scheduling across more than one agricultural season. This was not simply a matter of sowing twice. Seed selection, field preparation, weeding, harvesting, threshing, drying and storage had to be coordinated with livestock care and domestic work. Double-season cultivation could increase total output and smooth food availability, but it also concentrated labour demands at particular moments. The household economy therefore depended upon temporal organisation as much as upon land area.

10.6 Pulses, oilseeds and minor crops mattered to resilience

Cereals dominate many historical narratives because they are easily linked to taxation and staple consumption, but archaeobotanical evidence reveals a broader agrarian portfolio. Pulses contributed protein and could be fitted into seasonal rotations; oilseeds and fibre crops added food, fuel, craft and exchange value; gathered fruits and wetland resources supplemented cultivation. The appearance and diversification of such crops across Iron Age and early historic contexts in the Ganga Plain is evidence for planned arable systems rather than a subsistence regime organised around one cereal (Pokharia et al. 2017).

Figure 37 — A schematic annual agrarian calendar for the Middle Ganga plains

Figure 37 — Schematic annual agrarian calendar for the Middle Ganga plains. It shows seasonal coordination, not a fixed calendar for every locality.

10.7 Livestock linked cultivation, transport, food and wealth

Cattle, buffalo, sheep, goats and pigs had multiple economic roles. Bovids could provide traction, manure, milk and transport as well as meat; smaller stock converted vegetation and household waste into usable products and served as mobile stores of value. Archaeozoological evidence from Chirand shows a mixed domestic and wild animal economy, while early texts routinely place cattle-keeping alongside farming. Rural production should therefore be modelled as agro-pastoral rather than as crop cultivation separated from animal management.

10.8 Iron tools enabled some tasks but did not cause agriculture by themselves

Iron axes, sickles, hoes and plough-related implements could improve woodland clearance, harvesting and cultivation, and their wider availability formed part of the technological background to early historic expansion. But the older “iron caused the second urbanisation” model is too mechanical. Farming had existed long before widespread iron; productivity depended equally on seed systems, labour, soil, water, livestock and social organisation. Iron should be treated as one enabling element in a coupled agrarian system, not as a single trigger (Sharma 1983; Thapar 1999; Allchin 1995).

10.9 Floodplains offered fertility and danger together

The north Bihar plain was not a stable agricultural platform. Natural levees, backswamps, abandoned channels, wetlands and younger alluvial surfaces created sharply different field conditions over short distances. Flood deposition could renew soil nutrients or bury crops and settlements; channel migration could improve one locality while damaging another. Chapter 5 showed why this geomorphic dynamism matters archaeologically. For farmers it also meant that land quality was historical: the productive value of a plot depended upon elevation, drainage, sediment and the recent behaviour of rivers.

10.10 Rainfall was fundamental; large irrigation systems must not be invented

The monsoon provided the principal water regime for much of the eastern Gangetic plain, supplemented locally by floodwater, ponds, wells, channels and stored water. The Arthaśāstra devotes detailed attention to rainfall, land types and irrigation works, showing the conceptual importance of water management in later

statecraft (Bhattacharya 1978). That evidence should not be transformed into a claim that Vaishali, Mithila or Anga possessed a uniform state-built canal network in the earlier period. Where local archaeological or inscriptional proof is absent, the responsible formulation is that irrigation and water control were possible at several scales but remain unevenly documented.

10.11 Water management operated at household, community and political scales

Even without monumental canals, agrarian water management could involve field bunds, drainage, use of natural depressions, ponds, wells and maintenance of local channels. Some forms required only household labour; others demanded cooperation among neighbours or intervention by political authorities. The social history of irrigation is therefore not simply a technical question. Access to water could magnify inequality when households differed in labour, livestock, location or political influence. Conversely, collective maintenance could bind a settlement together through shared dependence on infrastructure.

10.12 The Kūṭadanta Sutta links seed, cattle and public order

A striking early Buddhist political-economic narrative appears in DN 5, the Kūṭadanta Sutta. Faced with disorder, the king is advised not merely to punish or levy fresh taxes but to provide food and seed-grain to those engaged in farming and cattle-keeping, capital to traders, and food and wages to government servants. The passage is not a royal budget from historical Magadha, yet it reveals a social imagination in which agrarian inputs, livelihoods, revenue and political stability are explicitly connected (Walshe 1995, DN 5). It is especially valuable because it treats cultivators as economic actors whose productive capacity affects the wider state.

10.13 The household was the basic productive institution, but households were unequal

Agricultural production normally required coordinated household labour across seasons: field work, livestock care, food processing, fuel collection, storage, repair and childcare. The category *gahapati* in Pāli literature could denote the master of a household and, in many contexts, a person controlling substantial resources. It should not be translated automatically as “peasant” or “landlord” in every occurrence. The term is historically useful precisely because it shows that household authority and economic resources could be joined, while the size and wealth of such households varied greatly (Chakravarti 1987).

10.14 Control over land and labour created rural differentiation

Early historic rural society was not economically level. Some households possessed more land, cattle, seed, storage and labour than others. Pāli sources distinguish wealthy householders from dependent workers and frequently mention *dāsa* and *kammakāra* relationships. Such categories do not supply a census, but they demonstrate that cultivation could involve unequal control over people and productive assets. Landless labourers, servants, hired workers, debtors and smaller cultivators must therefore remain visible in the reconstruction even when elite householders dominate named narratives (Sharma 1983; Chakravarti 1987).

10.15 Village leadership linked local society to wider authority

The village was also an administrative and social node. Later sources make village headmen and local officials highly visible, but early evidence is less systematic. It is safer to reconstruct functions than fixed offices: coordination of local obligations, communication with rulers, dispute mediation, organisation of

labour, and collection or transmission of dues all had to occur somehow as territorial states expanded. The degree to which these functions were hereditary, elected, appointed or informal probably varied. A single later administrative template should not be projected across all of Vajji, Anga and Mithila.

10.16 Taxation depended on production but cannot be assigned a universal rate

States and oligarchic polities required resources for officials, warfare, public works, courts and ritual or diplomatic expenditure. Agriculture therefore became an important base for appropriation. Yet the exact incidence of tax in early Mithila–Vajji–Anga cannot be reconstructed by importing the rates prescribed in later legal or statecraft texts. The Arthaśāstra distinguishes countryside revenues and agricultural dues from urban revenues, demonstrating a developed fiscal logic, but the text belongs to a different evidentiary layer (Bhattacharya 1978; Olivelle 2013). For the earlier period, the secure conclusion is that expanding political institutions required regular access to rural surplus, not that one universal percentage applied everywhere.

10.17 Surplus had several claims before it ever reached a market

A harvest did not divide neatly into “subsistence” and “surplus.” Seed for the next season, household food, fodder, payments to workers, social obligations, ritual gifts, taxes or dues, repayment of debts and emergency reserves could all claim shares. Only some produce entered exchange. This is why storage capacity and access to labour mattered so much. A household with the same gross harvest as its neighbour could have a very different economic position if its dependants, debts, livestock needs or political obligations were greater.

Figure 38 — Rural production and the competing claims on surplus

Figure 38 — Rural production and the competing claims on surplus: reproduction, reserves, labour, exchange, taxation and gifts drew on the same harvest.

10.18 Storage turned harvests into year-round security and bargaining power

Archaeological evidence for bins, pits, jars, granaries and processing areas varies by site, and not every storage feature can be tied to a specific social institution. Nonetheless, storage is fundamental to any seasonal cereal economy. It bridged the gap between harvests, preserved seed, buffered bad seasons and made taxation

or trade possible after the moment of harvest. Larger stores could also create power: households or institutions able to retain grain could lend, redistribute, sponsor dependants or survive price shocks more effectively than those living close to immediate consumption.

10.19 Rural and urban economies were mutually dependent

Vaishali and Champa could not have been sustained by urban crafts and commerce alone. Town populations required grain, vegetables, livestock products, fuel, timber and labour from surrounding countryside. In return, rural households gained access to specialised crafts, metal tools, salt, ornaments and larger markets. The *Arthaśāstra*'s distinction between city and countryside revenues and its provisions for agricultural goods entering towns belong to a later administrative text, but they illuminate a structural relationship also visible archaeologically: urbanisation increased the density and regularity of rural–urban flows (Bhattacharya 1978; Allchin 1995).

10.20 Vaishali must be understood with its agrarian hinterland

Excavations at Vaishali document a major early historic settlement sequence, fortification and material culture, but excavation inside an urban mound cannot by itself reconstruct the fields that fed the city (Sinha and Roy 1969). The agricultural history of Vaishali therefore requires a hinterland perspective: nearby villages, seasonal routes, cattle movement, wetlands and grain flows are analytically necessary even where they are archaeologically less visible. The city's political and religious institutions were ultimately supported by productive landscapes beyond its walls.

10.21 Chirand demonstrates long-term agrarian continuity within a riverine economy

Chirand is especially valuable because its long sequence links prehistoric farming to later cultural phases. Its earlier levels already show rice, wheat, barley, pulses, domestic animals, fishing and hunting. The lesson for early historic history is not that every later practice remained unchanged, but that urban-period agriculture rested on a deeply established regional knowledge of crops, animals and riverine resources. Rural transformation could therefore proceed through intensification and reorganisation of existing practices as well as through technological innovation.

10.22 Senuwar is a comparator for agricultural complexity, not a substitute for Mithila

Senuwar, south of the Ganga, provides unusually detailed evidence for crop history, animal use and long-term farming communities (Singh 2004). Its evidence helps identify mechanisms—multi-cropping, crop diversification, household processing, agro-pastoral integration—that are plausible in the wider Middle Ganga world. But Senuwar is not located in Vaishali, Anga or Nepal-side Mithila. Its role in this chapter is comparative: it demonstrates what archaeobotanical evidence can reveal and what a complex farming system could look like, while local claims still require local support.

10.23 Champa and Anga joined agrarian production to riverine exchange

Champa's early historic importance derived partly from its position within the Ganga-linked transport world. Excavations demonstrate a substantial fortified settlement with Northern Black Polished Ware and later occupation, but published archaeological summaries are much stronger on fortification, ceramics and structures than on a complete local agricultural dataset. It is reasonable to infer an agrarian hinterland

necessary to sustain the city, yet the crops, landholding patterns and tax arrangements of that hinterland should not be supplied from later texts as if directly excavated. Anga's rural economy must therefore be written through the conjunction of urban archaeology, regional agriculture and explicitly marked inference.

Figure 39 — Evidence control for the rural economy of Mithila-Vajji-Anga

Claim strength decreases when evidence is farther from the place, date or question being reconstructed.

Figure 39 — Evidence control for the rural economy of Mithila-Vajji-Anga: local archaeology has the strongest place-specific claim; more distant evidence requires stronger qualification.

10.24 Woodland, grazing and commons were part of agrarian production

Cultivation depended on resources outside cultivated plots. Grazing areas sustained cattle; wetlands supplied fish, reeds and fodder; woodland provided fuel, timber, fruits and materials. Expansion of fields could therefore create competition among agriculture, pasture and forest use rather than simply “conquer wilderness.” The Arthaśāstra’s later categories of productive countryside, pasture and protected landscapes remind us that agrarian states had to think about several land uses, but local boundaries and rights in early Mithila-Vajji-Anga remain poorly documented (Olivelle 2013).

10.25 Rural households managed recurrent risk rather than stable averages

Monsoon delay, excessive rain, flood, river migration, crop disease, livestock loss, conflict and insecurity could all disrupt production. The Kūṭadanta Sutta’s concern with unsafe roads, plundered villages and seed support makes clear that political disorder itself could become an agrarian risk. Households responded through crop diversity, livestock, storage, kin support, mobility and access to wetlands or markets. These mechanisms should not be romanticised as perfect resilience; repeated shocks could produce debt, dependence and loss of productive assets.

10.26 Gendered agricultural labour is under-recorded, not absent

Chapter 9 showed how textual archives disproportionately preserve elite, religious or exceptional women. The same bias affects agrarian history. Sowing, transplanting where practised, weeding, harvesting, threshing, winnowing, animal care, food processing, storage and fuel or fodder collection could involve women as well as men, but early sources rarely quantify the division of labour. A responsible social history therefore avoids

both extremes: it does not erase women from agriculture, and it does not project a modern ethnographic task-list unchanged into the first millennium BCE.

10.27 Servitude and hired labour were part of the countryside

Terms such as *dāsa* and *kammakāra* in early Buddhist literature show that dependent and hired labour existed alongside household production. The precise legal meanings varied by context and should not be flattened into a single modern category of “slave” or “wage labourer.” Economically, however, they demonstrate that some households could command labour beyond a narrow nuclear family. This matters for agriculture because land, cattle and seed could only generate output when sufficient labour was available at time-sensitive stages of the farming cycle (Chakravarti 1987; Sharma 1983).

10.28 Monasteries depended on rural surplus even when they did not farm

Buddhist and Jain renunciant institutions were embedded in agrarian economies. Monastics depended upon lay gifts of food, cloth, medicine and residences; donors’ ability to give was ultimately connected to household and market production. Wealthy urban patrons could mediate these flows, but grain and other primary products originated in rural landscapes. This relationship should not be simplified into a universal model of monastery-owned land for the early period. The secure point is institutional dependence on surplus and redistribution, not a claim that every monastery possessed agricultural estates.

10.29 Nepal-side Mithila requires explicit evidentiary restraint

For the early historic Tarai and Nepal-side Mithila, settlement archaeology has expanded, but evidence for specific field systems, household landholding and crop regimes remains uneven. The ecological continuity of the Gangetic foreland makes certain agrarian mechanisms plausible, while political and cultural connections make comparison necessary. Yet later Maithil tenancy, irrigation or caste arrangements cannot be back-projected into antiquity. Where direct archaeobotanical or inscriptional evidence is absent, this volume will state the gap rather than fill it with customary practice documented centuries later.

10.30 Conclusion: the rural economy was a network of production, risk and power

Early historic agriculture in Mithila, Vajji and Anga should be understood as a historically changing system linking crops, animals, water, labour, storage, exchange and political obligation. Its roots extended deep into earlier farming traditions, while urbanisation increased the scale and regularity of surplus flows. Rural households were unequal; *gahapatis*, dependants and workers did not occupy the same economic position. States and religious institutions depended upon countryside production, but the precise forms of taxation, irrigation and landholding varied and are not always locally recoverable. The most defensible reconstruction is therefore neither a self-sufficient village idyll nor a fully bureaucratised agrarian state imposed everywhere at once, but a mosaic of productive landscapes increasingly tied to towns, institutions and political power. Chapter 11 turns to the crafts and technologies that converted rural and urban raw materials into specialised goods.

Table 10.1 — Agricultural evidence, interpretive value and limits

Evidence base	What it can support	What it cannot prove alone
Chirand	Long sequence; rice, wheat, barley, pulses; domestic animals; fishing	Strong for regional farming history; does not by itself establish

Evidence base	What it can support	What it cannot prove alone
	and processing evidence.	Vaishali/Anga land tenure or tax rates.
Senuwar	Detailed crop, animal and farming evidence from Neolithic through later phases.	Excellent Middle Ganga comparator; geographically outside Mithila–Vajji–Anga proper.
Vaishali	Early historic urban sequence, fortification and material culture.	Demonstrates a major consuming/administrative centre; agricultural hinterland must be reconstructed cautiously.
Champa / Anga	Fortified early historic settlement and NBPW-related occupation.	Supports urban-riverine economy; local crop and tenure evidence is less complete in published summaries.
Early Buddhist texts	Farmers, cattle-keepers, gahapatis, dependants, taxes/revenue discourse; DN 5 links seed support to production.	Social and institutional vocabulary; literary/religious genres, not local farm surveys.
Arthaśāstra	Detailed land, rainfall, irrigation, rural revenue and state administration.	Powerful comparative model, but composite/late and not direct evidence for every early regional polity.

CHAPTER 11 — CRAFTS AND TECHNOLOGY

Craft history asks how knowledge, materials, labour and exchange were combined to make useful and valued objects. The archaeological record of Mithila, Vajji and Anga preserves pottery, metal tools, ornaments, beads, terracottas, bone and ivory objects, bricks and other durable remains, but it preserves wood, fibre, leather and many workshop installations much less reliably. The presence of a finished knife, bead or fine pot therefore cannot automatically be converted into proof of a local workshop. Conversely, the absence of textiles or carpentry debris cannot be treated as proof that spinning, weaving or woodworking were unimportant. This chapter reconstructs craft production by matching each claim to the evidence actually available at Chirand, Vaiśālī, Panda, Champa and related Middle Ganga sites, while using better-preserved comparator sites only to clarify technological possibilities rather than to fill local gaps (Sinha and Roy 1969; Verma 1971; Chakrabarti 2009).

11.1 Technology was social knowledge, not a list of inventions

A technology is a sequence of learned actions: selecting material, preparing it, controlling heat or force, shaping the object, finishing it, maintaining tools and judging quality. These skills were transmitted through observation, apprenticeship and repeated practice. For early historic society, the most defensible questions are therefore not simply when iron, the potter's wheel or glass appeared, but who controlled particular techniques, how raw materials reached settlements, whether production occurred in households or specialist settings, and how finished goods circulated. Archaeology can sometimes recover this operational sequence, but only when production debris and installations survive alongside finished artefacts.

11.2 A finished object does not prove a workshop

This distinction is crucial for the present region. Excavations at Vaiśālī yielded pottery, terracotta and stone ornaments, metal objects and other manufactured goods, while Panda produced iron tools and weapons, semi-precious-stone beads, copper ornaments and ivory objects in different phases. Such finds securely establish use and circulation. Local manufacture becomes a stronger claim only when excavators recover raw material, blanks or unfinished pieces, specialised tools, moulds or crucibles, furnaces, slag, wasters or concentrations of production waste. In their absence, the object may have been made elsewhere and exchanged into the settlement (Sinha and Roy 1969; Archaeological Survey of India 1993–94).

CRAFT TECHNOLOGY IS A SEQUENCE OF DECISIONS, NOT A SINGLE OBJECT

Workshop identification becomes strongest when several stages—raw material, unfinished pieces, tools, furnaces or slag, and waste—occur together.

Figure 40 — The craft production chain: raw material, preparation, transformation, finishing, circulation and repair/discard form a sequence of technological decisions.

11.3 Craft specialisation existed in degrees

Specialisation should not be imagined as a binary contrast between self-sufficient households and factory-like workshops. Some tasks could be seasonal household crafts; others required part-time specialists; still others demanded expensive pyrotechnology, trained drilling or polishing, or access to distant raw materials. Standardised products may suggest routinised skill, but standardisation alone does not reveal whether production was controlled by a state, guild, merchant, household or itinerant artisan. Comparative archaeology across early historic South Asia shows that craft production could be spatially dispersed even when towns created dense markets for specialist goods (Allchin 1995; Chakrabarti 2009).

FROM OBJECT PRESENCE TO WORKSHOP PROOF

Object presence proves use or circulation; workshop proof requires evidence from production stages.

Figure 41 — Evidence for local production becomes stronger when finished objects are joined by tools, raw material, unfinished pieces, waste and production features.

11.4 Pottery was the largest surviving craft archive

Ceramics dominate excavated assemblages because fired clay survives where baskets, wooden vessels and cloth decay. The Middle Ganga sequence includes black-and-red ware, black slipped ware, red and grey wares and, in the early historic horizon, Northern Black Polished Ware. Variation in fabric, firing, surface treatment, wall thickness and vessel form reflects technological choices. Yet a ceramic category is not equivalent to an ethnic group or single production centre. Similar wares could be made at multiple places, exchanged across regions, copied locally or produced to shared standards. The archaeological challenge is to distinguish style circulation from workshop organisation.

11.5 Northern Black Polished Ware reveals skill but not one centralised industry

NBPW required unusually careful clay preparation, forming, surface treatment and firing to create its characteristic fine fabric and lustrous surfaces. Its wide distribution makes it an important marker of intensified interregional interaction, but it should not be treated as the product of one royal industry or as a mechanical index of urban status. At Panda, the NBPW phase was accompanied by black slipped, grey, black and red wares; the assemblage therefore represents a ceramic economy with several production traditions operating together rather than one luxury ware replacing everyday pottery (Archaeological Survey of India 1993–94).

11.6 Pottery manufacture linked countryside resources to urban demand

Potters required clay sources, temper or other inclusions, water, fuel, drying space and firing facilities. Large settlements increased demand for cooking pots, storage jars, serving vessels, lamps, lids, ritual containers and construction ceramics. The resulting industry was therefore tied to the ecology around towns as much as to urban consumers. Even when a kiln has not been excavated, the quantity and diversity of ceramic vessels can indicate sustained production somewhere within the settlement's economic catchment. Where kiln wasters or firing installations are absent, however, the exact place of manufacture should remain open.

11.7 Iron working must be separated into smelting, smithing and use

Iron is often discussed as though every iron artefact records local metallurgy. In fact, ore smelting, bloom consolidation, forging, sharpening and repair are distinct stages that may occur at different places. The strongest evidence for primary smelting includes ore, furnaces and slag; smithing is indicated by hearths, hammer scale, slag and unfinished or repaired objects; finished tools alone establish use. Early iron in the Middle Ganga plain predates the full early historic urban phase at several sites, while Bihar sites including Chirand have iron in Black-and-Red-Ware contexts. This long chronology cautions against an 'iron revolution' in which urban crafts suddenly appear at one date (Chakrabarti 2009).

11.8 Panda shows a diversified iron-tool repertoire without proving local smelting

The NBPW phase at Panda in Samastipur produced iron knives, sickles, daggers and spearheads, together with fine pottery and beads. These objects reveal agricultural, domestic and martial uses of iron and show that iron had become embedded in daily and political economies. But the published summary does not, by

itself, document ore reduction or a smelting furnace at the site. The correct historical statement is therefore that Panda participated in a developed iron-using economy; whether every object was smelted and forged locally remains a separate archaeological question (Archaeological Survey of India 1993–94).

11.9 Copper and copper alloys occupied different technological niches

Copper did not disappear when iron spread. Hooks, earrings, rods, bangles, vessels and coins could exploit copper's malleability, appearance and resistance to corrosion. At Panda, a copper hook occurs in the Chalcolithic phase and copper earrings in a later urban horizon. Vaiśālī also yielded copper objects and ornaments. These finds illustrate technological coexistence: material choice depended on function, cost, social value and available skill. A stronger metal did not automatically replace a more workable or visually valued one.

11.10 Chirand preserves an exceptional tradition of bone and antler working

Chirand is indispensable because its early levels preserve a wide range of bone and antler tools—celts, scrapers, chisels, hammers, needles, points, borers, awls, diggers and arrowheads—as well as ornaments. Verma also reported unfinished implements, demonstrating production rather than mere consumption. This evidence belongs primarily to the Neolithic history treated in earlier chapters, but it establishes a deep regional repertoire of cutting, scraping, drilling, polishing and shaping organic materials. It would be unsafe to assume unchanged artisan lineages into the early historic period; the defensible continuity is technological possibility and long familiarity with animal-derived raw materials (Verma 1971).

11.11 Bone and ivory continued beside metals because materials were functionally different

Bone and ivory could be cut, polished, drilled and carved into points, handles, needles, ornaments, combs and small implements. Their continued use need not be explained simply as a cheap substitute for metal. Lightness, elasticity, colour, availability and suitability for fine carving made organic materials useful in their own right. Panda's later levels yielded ivory objects, while other early historic sites in the broader Ganga system show bone points and carved ivory. As with metal, finished pieces establish use; unfinished blanks and production debris are required before claiming a local ivory workshop.

11.12 Stone beads reveal both skill and long-distance material movement

Carnelian, agate, chalcedony, crystal and other semi-precious stones were transformed through chipping, grinding, drilling, heat treatment in some traditions and polishing. Their geological sources were unevenly distributed, so bead assemblages can signal exchange even when production occurred elsewhere. Vaiśālī and Panda yielded stone beads; their presence links consumers to wider raw-material and craft networks. Ethnoarchaeological studies of Indian beadmaking demonstrate how many specialised stages may lie behind a small finished bead and warn against identifying a workshop without manufacturing waste (Kenoyer, Vidale and Bhan 1991).

11.13 Terracotta beads and ornaments represent a different economy from rare stones

Terracotta beads, ear ornaments, bangles and pendants could be made from locally available clay with lower raw-material costs than carnelian, crystal or glass. Vaiśālī produced numerous terracotta ornaments alongside stone examples. This coexistence suggests differentiated consumption rather than a simple

evolution from cheap to expensive materials. Shape, finish and context mattered as much as raw material. Terracotta also demonstrates how craft categories overlapped: a potter or clay specialist could produce vessels, figurines, discs, toys, beads and architectural ceramics using related but not identical skills.

11.14 Glass was technologically demanding, but beads do not automatically prove glassmaking

Glass production required high-temperature pyrotechnology and control over silica, fluxes and colourants; bead manufacture could then involve winding, drawing, cutting or reheating pre-existing glass. Early historic eastern India participated in expanding glass-bead networks, but the distinction between making glass and making beads from glass is fundamental. A settlement with glass beads may have imported finished beads, imported glass cane or produced beads locally. Production is best demonstrated by rods, tubes, cullet, failed beads, furnaces or characteristic waste. The broader South Asian literature shows why manufacturing technique must be reconstructed from debris and context, not bead presence alone (Kanungo 2004; Kanungo 2021).

11.15 Shell working connected riverine interiors to distant ecological zones

Shell ornaments are valuable because raw material origin can differ sharply from the place of use. Freshwater shell was locally accessible in the riverine plains, while marine conch required longer-distance movement. Bangles, discs and ornaments therefore combined craft skill with exchange. Sawn shell, blanks or large quantities of working waste are stronger evidence for local manufacture than finished bangles. The presence of shell in inland towns belongs to the same history of circulation that moved semi-precious stone, metal and perhaps specialised glass products.

11.16 Textile technology is archaeologically underrepresented

Clothing, cordage, sacks, nets, mats and household textiles were fundamental to daily life, but plant and animal fibres survive poorly in humid alluvial environments. Spindle whorls, loom weights, needles, impressions and occasional mineralised fibres can provide indirect evidence, while texts attest the social importance of cloth and robe donation. The evidentiary rule must remain strict: a textual reference to cloth in early Buddhist society does not prove a specific loom technology at Vaiśālī, and the absence of preserved fabric does not prove that weaving was absent. Textile history therefore requires a combined archaeological and textual method with explicit uncertainty.

11.17 Spinning and weaving could cross household and specialist domains

Fibre preparation and spinning are tasks that can be embedded in household routines, while certain forms of weaving, dyeing or finishing may require dedicated skill and equipment. Production could therefore shift between domestic and specialist settings without leaving a clear architectural boundary. This matters for social history because craft specialisation is not synonymous with male workshop labour. Where the evidence does not identify the workers, gender should not be assigned automatically. Later ethnographic analogies may generate questions, but they cannot identify the gender of early historic spinners or weavers at a particular site.

11.18 Carpentry was essential precisely where archaeology is weakest

Posts, rafters, doors, carts, boats, agricultural implements, furniture, handles and storage structures required woodworking, yet tropical wood usually decays. Post-holes and impressions may preserve the

location of timber architecture while iron nails or clamps survive after the wood disappears. Riverine transport also presupposed boat-building and repair skills, but surviving boats are rare. A material history based only on durable artefacts therefore systematically underestimates carpenters and other workers in perishable media.

11.19 Brick and earthen construction were technologies of organised labour

Early historic settlements increasingly used burnt brick, rammed floors, plaster, drains, wells and other built features alongside timber and earth. Brick production required clay preparation, moulding, drying, fuel, firing and transport; construction required measurement and coordinated labour. At Vaiśālī, burnt-brick structures, floors, fortification and water-management features show sustained investment in built space. Such structures reveal technical organisation, but they do not by themselves tell us whether labour was *corvée*, hired, household-based or controlled by a corporate body (Sinha and Roy 1969).

11.20 Ring-wells and drains show ceramic engineering, but chronology matters

Ring-wells are composed of standardised fired ceramic rings fitted vertically to manage water or soakage in dense settlements. Their manufacture demanded moulding or forming large repeated units and successful firing. Yet ring-wells belong to different dates at different sites. At Panda, four ring-wells are specifically reported in the Kushana horizon, later than the NBPW phase. They must therefore not be backdated simply because ring-wells are broadly associated with early historic urbanism elsewhere (Archaeological Survey of India 1993–94).

11.21 Standardisation does not automatically imply state control

Repeated brick sizes, vessel forms, beads or metal objects can indicate shared conventions, templates, specialist training or market demand. They do not automatically demonstrate a royal department or guild. Production can become standardised through apprenticeship networks, consumer expectation, itinerant artisans or competition among workshops. The same caution applies to NBPW, coins and architectural units. Centralisation is a political-economic claim that requires evidence beyond formal similarity.

11.22 Workshops were workplaces, but not all craft labour occurred in workshops

Archaeologists often search for furnaces, kilns and concentrated waste because these features make production visible. Yet many crafts could occur in courtyards, house fronts, seasonal work areas or temporary shelters. Repair work might be mobile. Pottery could be fired beyond dense habitation because of smoke and fire risk. A town may therefore depend heavily on craft production while preserving only part of its productive landscape inside excavated trenches. Urban excavation must be connected to suburban and rural survey before craft geography can be reconstructed confidently.

11.23 Household production and specialist production were interconnected

Households consumed tools, pots, ornaments and cloth, but they could also produce thread, food-processing equipment, simple clay objects or repaired goods. Specialist artisans depended in turn on household demand, rural raw materials and food supplied by cultivators. This interdependence prevents a sharp analytical division between ‘craft economy’ and ‘rural economy’. Chapter 10 traced surplus from countryside to towns; craft history shows the reverse flow of tools, containers and valued goods back into rural life.

11.24 Gendered craft labour is often hidden by the archive

Craft histories can reproduce textual and archaeological bias by assigning visible tools to men and invisible fibre or household production to women. The evidence rarely supports such certainty. Women certainly participated in household production and textile work in many later South Asian contexts, but a direct early historic attribution requires local evidence. The safer reconstruction recognises that craft labour was organised through households, dependence, apprenticeship and specialist networks while leaving worker identity open where sources are silent.

11.25 Raw materials made crafts regional before finished goods reached markets

No major settlement possessed every needed raw material. Fuel, clay, timber, bone, fibres, stone, ores, shell and colouring agents came from different ecological zones. This distributed geography meant that craft production depended on transport and exchange before a finished object entered a market. River corridors were particularly important in the study region. The Ganga and its tributaries could move bulky materials and finished goods, linking Champa and other eastern centres to wider networks while also connecting north-bank settlements to crossing points and market towns.

CRAFT PRODUCTION AS A DISTRIBUTED REGIONAL NETWORK

Specialisation can be dispersed across households, mobile artisans, workshops and exchange nodes; urban demand does not require every craft to be produced inside the city wall.

Figure 42 — Craft production as a distributed regional network linking resources, households, specialist workshops, markets, urban consumers, institutions and repair/recycling.

11.26 Vaiśālī was a major consumer and craft environment, but workshop claims must remain specific

The Vaiśālī excavations document ceramics, terracottas, ornaments, metal objects, beads and substantial architecture across a long early historic sequence. The diversity is consistent with a large settlement in which specialist production, exchange and repair were important. Yet the published corpus also demonstrates the methodological difference between artefact diversity and manufacturing proof. Unless raw material, unfinished pieces, tools and waste are tied to a specific context, the safest conclusion is that Vaiśālī participated in extensive craft and exchange systems rather than that every recovered object was made inside the city (Sinha and Roy 1969).

11.27 Panda provides unusually useful evidence for technological coexistence

Panda's sequence brings several technologies into one stratigraphic narrative. The Chalcolithic phase included stone implements, a copper hook, bone arrowheads and pottery; the NBPW phase yielded finely prepared ceramics, iron knives, sickles, daggers and spearheads, and semi-precious-stone beads; later levels added brick construction, ring-wells, copper earrings and ivory objects. The sequence demonstrates coexistence and accumulation rather than simple replacement: stone, bone, copper, iron, clay and ivory remained useful in different technical roles (Archaeological Survey of India 1993–94).

11.28 Chirand shows why technological history requires the *longue durée*

Chirand's importance is not that one craft tradition remained unchanged for millennia, but that the site preserves successive technological repertoires across major cultural transitions. Its bone industry, ceramics, stone tools and later metals show repeated adaptation to new materials without erasing older skills immediately. This *longue durée* cautions against narratives in which a single innovation—copper, iron, wheel-made pottery or urban demand—suddenly transforms every productive practice. Technology accumulated, recombined and became socially reorganised over time.

11.29 Champa and Anga belonged to a craft-and-exchange corridor, but production locations remain unevenly known

Excavations at Champa establish a substantial early historic settlement with NBPW and other ceramics, fortification, structural investment and a material assemblage connected to wider exchange. Its position near the Ganga made it well placed to receive raw materials and distribute finished goods. Yet the published archaeological summaries do not justify turning Champa into a universal manufacturing centre for every craft found in Anga. The correct scale of claim is that urban demand, transport connectivity and recovered artefacts make craft production and exchange integral to Champa's economy, while the location and organisation of individual industries require craft-specific evidence (Archaeological Survey of India 1970–76).

Figure 43 — Preservation bias: pottery and stone are much more visible archaeologically than wood, textiles and fibres. The bars are schematic, not measured values.

11.30 Nepal-side Mithila and conclusion: technological absence may be an archive problem

For early historic Nepal-side Mithila, archaeological publication remains uneven for many categories of workshop evidence. The absence of excavated furnaces, textile installations or bead workshops in a particular published record must therefore be distinguished from the absence of the craft itself. Across Mithila, Vajji and Anga, the strongest conclusion is that early historic technology formed a network of material knowledge linking households, specialists, rural resources, towns, markets and institutions. Pottery and brick survive abundantly; metal, stone, bone and glass survive selectively; wood and textiles are strongly underrepresented. A defensible craft history therefore ranks evidence by production stage and preservation potential, rather than filling silent parts of the record with assumed guilds, fixed artisan castes or state-controlled industries. Chapter 12 follows these objects beyond production into trade, merchants and markets.

Table 11.1 — Craft evidence, what it can establish, and what it cannot establish alone

Evidence	Supports	Does not establish by itself
Pottery fabrics, forms, wasters, kilns	forming, firing, consumption; local manufacture where kilns/wasters occur	ethnicity, political identity, or one centralised production centre
Iron tools and weapons	use of iron and functional repertoire	local smelting without ore/furnace/slag; local smithing without smithing debris
Copper objects	continued use of copper/copper alloys	local casting or alloying without moulds, crucibles or waste
Beads of stone or glass	consumption, ornament, exchange and material connectivity	local beadmaking without blanks, drills, rods/tubes, cullet or failed pieces
Bone / ivory objects	use and fine working of organic materials	continuous artisan lineage or local workshop without unfinished pieces/waste
Brick, drains, ring-wells	construction skill, organised labour and water-management technology	a specific labour regime or universal chronology across sites
Text / iconographic reference to cloth or craft	social valuation, terminology and possible practices	a particular archaeological technique or workshop at a named settlement
Absence of wood or textiles	limits of preservation	absence of woodworking, weaving, cordage or baskets

Chapter 12 — Trade, Merchants and Markets

Chapter argument. Trade in early Mithila–Vajji–Āṅga is best reconstructed as a set of overlapping local, regional and long-distance exchanges rather than as one integrated “market economy.” Archaeology establishes movement of materials and objects; early Buddhist and Jain texts reveal categories of merchants, journeys and transactions; rivers and roads supplied the spatial infrastructure; and urban centres such as Vaiśālī and Campā concentrated demand, craft production, finance and redistribution. Each source illuminates a different scale, and none by itself proves traffic volume, prices, merchant institutions or political control.

12.1 Trade must be reconstructed from converging evidence

Commercial history is unusually vulnerable to overstatement because portable objects travel for many reasons. A bead at Vaiśālī may have arrived through exchange, gift, pilgrimage or personal mobility; a punch-marked coin may indicate monetised transaction, savings, tax payment or later deposition. Conversely, written accounts of merchants do not automatically identify excavated marketplaces. The strongest reconstruction therefore combines artefact provenance, distribution, settlement hierarchy, transport geography and texts. This approach follows the material-context emphasis of Allchin et al. (1995), Chakrabarti (2009) and Chakravarti (2001, 2020). It also prevents literary journeys from being converted into maps of measured trade. In this chapter “trade” is used broadly for repeated exchange beyond immediate household reciprocity, while “market” is reserved for institutionalised or recurrent places and occasions of transaction.

No single artefact, text, or place-name is sufficient by itself.

Figure 44 — Trade reconstruction is strongest when archaeology, texts, landscape and institutions converge.

12.2 Exchange was older than cities and broader than formal markets

The preceding chapters showed that stone, shell, copper, beads and specialised ceramics circulated before the full early historic urban horizon. Urbanisation intensified these flows, but did not create exchange from

nothing. Village households exchanged food, labour, livestock, tools and craft products; itinerant traders could link small settlements to larger centres; and urban demand drew surplus and raw materials from rural zones. This layered model is important because the archaeological visibility of a large town should not erase the less visible exchanges that sustained it. Chakravarti's work on early Indian commerce similarly cautions against reducing trade to luxury goods or distant voyages: everyday agrarian and craft commodities mattered at local and regional scales as well (Chakravarti 2020).

12.3 Agrarian surplus and commerce were mutually dependent

Urban merchants and craft specialists depended on food supplied by cultivators, herders, fishers and processors. Rural households in turn needed salt, metal implements, ornaments, selected ceramics and services that were not equally available in every locality. Trade was therefore embedded in the agrarian economy rather than opposed to it. The early Buddhist category *gahapati* could encompass substantial householders whose wealth rested on land, business or both; the *setṭhi* represented another form of urban economic prominence (Liu 2022). These categories should not be forced into modern classes, but they demonstrate that agricultural surplus, household wealth and commerce interacted. The rural–urban relationship was a circulation system, not a one-way extraction of food into towns.

12.4 Rivers were transport corridors, resource zones and risk environments

The Ganga and its tributaries offered lower-friction movement for bulky loads than many overland routes, especially in a floodplain where seasonal channels, marshes and monsoon damage could complicate roads. River transport could move grain, timber, pottery, stone, salt and people, while ferries connected road segments on opposite banks. Yet navigability varied by season and channel. A settlement near a river is therefore not automatically a “port.” The stronger inference is that river proximity increased transport options. For Campā, its location in the Bhagalpur Ganga corridor is central to understanding its commercial potential; for Vaiśālī, connections to Gandak-Ganga routes linked the republican centre with the wider Middle Ganga system.

12.5 Overland roads and caravan travel complemented river movement

Early Indian texts contain repeated images of caravan merchants, difficult roads, forests, river crossings and danger. The term *sārhavāha* is commonly used for a caravan leader, while *vaṇij* or *vāṇija* can denote a trader more generally. These terms indicate differentiated commercial roles, but they should not be treated as a fixed corporate hierarchy in every place. Overland routes were indispensable where rivers did not connect origin and destination directly, and they carried people, pack animals and high-value goods between towns and rural nodes. River and road should therefore be modelled as braided systems: goods could move by boat for one segment, ferry or cart for another, and caravan for a third.

12.6 Vaiśālī was a nodal urban market, not merely a political capital

Excavations at Vaiśālī yielded long sequences of ceramics, terracottas, beads, metal objects, coins and substantial architecture, indicating a large and materially diverse settlement (Sinha and Roy 1969). Such diversity is consistent with consumption, redistribution and specialised production. Buddhist texts also remember wealthy householders, public spaces and institutional patronage around Vesālī. Neither archaeology nor literature gives a recoverable price list or a street-by-street bazaar plan, but together they support the interpretation of Vaiśālī as a major nodal market within the northern Middle Ganga plain. Its

political importance would itself have generated demand from assemblies, visitors, retainers, religious communities and surrounding rural populations.

12.7 Campā joined political centrality to riverine commerce

Campā, capital of Aṅga, occupied a strategic position in the Ganga corridor near modern Bhagalpur. Excavation reports document early historic occupation with NBPW and other ceramic traditions, structural remains and fortification across successive seasons (ASI, Indian Archaeology — A Review, 1970–76). Early Buddhist geographical traditions also remember Campā as a major city among the eastern centres. Later Jātaka narratives associate merchants from Campā with long journeys, including sea-oriented stories. These literary memories are valuable evidence for Campā’s commercial reputation, but they are not direct shipping logs for the sixth century BCE. The secure conclusion is that Campā was a major urban node whose riverine location favoured exchange toward both the central Ganga basin and the east.

12.8 Mithilā, Vaiśālī and Aṅga belonged to overlapping corridors, not one fixed commercial territory

The historical regions named Mithilā/Videha, Vajji and Aṅga changed through time and should not be mapped as immutable economic provinces. Exchange crossed political frontiers. Roads from the north Bihar plain could connect Mithilā and Vaiśālī to the Ganga crossings; eastward river movement could reach the Aṅga-Bhagalpur corridor; southward connections joined Magadha and the uplands. The usefulness of a regional history lies precisely in following these connections without asserting a timeless integrated “Mithila–Vajji–Aṅga market.” Commercial geography was made by routes, seasonal accessibility, political security and demand, and these changed faster than cultural memory often suggests.

12.9 Merchant terminology reveals diversity rather than a single merchant class

Pāli sources distinguish several commercial and household roles. Vaṇij/vāṇija is a broad term for trader; sārthavāha is associated with caravan leadership; seṭṭhi denotes a wealthy urban economic notable; gahapati describes a substantial householder and can overlap with agricultural or commercial wealth. Older scholarship sometimes converted such terms directly into modern categories such as banker, guild president or capitalist. A safer reading follows the contexts in which each term appears. Liu (2022) stresses the importance of gahapati and seṭṭhi as prominent supporters in early Buddhist cities, while Chakravarti (2001, 2020) emphasises the diversity of merchants and market forms. The categories indicate economic stratification, but not one uniform occupational corporation.

12.10 Seṭṭhi wealth could combine finance, trade and civic influence

The seṭṭhi of Buddhist literature is frequently portrayed as a wealthy urban figure able to mobilise resources, lend, donate and interact with rulers or religious institutions. Some seṭṭhis may have been deeply involved in trade; others may have managed wealth through credit, property and household enterprises. Because the texts are narrative and normative, they do not give accounting archives. The historical value lies in the social recognition of concentrated private wealth and its capacity to support institutions. This matters for Vaiśālī and other cities because religious patronage, building, food supply and hospitality required mechanisms for converting commercial or landed resources into public expenditure.

12.11 Retail, periodic markets and itinerant exchange are archaeologically difficult to see

A market can disappear without leaving a monumental structure. Temporary stalls, baskets, cloth awnings and wooden counters preserve poorly; periodic markets may reuse open ground; hawkers and itinerant traders leave even less distinctive evidence. Consequently, the absence of an excavated “marketplace” at a site does not prove the absence of market exchange. Archaeologists instead infer commercial activity from concentrations of weights, coins, seals, storage, imported materials, craft waste, roads and spatial clustering. Even then, inference must remain probabilistic. The most visible archaeological markets are often the ones with durable architecture, which biases historical reconstruction toward large towns.

Markets existed at several scales

Figure 45 — Markets and exchange operated at several nested scales, from households to long-distance networks.

12.12 Political authorities could tax and regulate exchange without creating it

States and oligarchic polities had incentives to protect routes, control ferries, levy dues and monitor strategic commodities. Later normative texts such as the Arthaśāstra describe elaborate offices for tolls, markets and trade, but their institutional detail should not be projected wholesale onto earlier Vaiśālī or Campā. They are best used comparatively to show the kinds of commercial problems states might seek to manage. Early commerce did not depend on a central state to exist: household exchange, itinerant trade and river traffic could operate across political boundaries. Political control modified transaction costs and security rather than constituting the entire commercial system.

12.13 Everyday commodities mattered more than a luxury-only model allows

Archaeology naturally highlights durable and attractive objects—beads, fine pottery, metals and ornaments. Yet the bulk of everyday exchange probably included commodities that survive poorly or are difficult to trace to origin: grain, pulses, oilseeds, salt, fish products, ghee, timber, fibres, textiles, baskets, fodder and livestock. Chakravarti (2020) explicitly argues against reducing early Indian trade to exotic portable luxuries and restores agrarian and everyday goods to commercial history. For Mithila–Vajji–Anga

this is especially important because floodplain agriculture and river transport could sustain movement of bulky staples even when archaeology records only the containers or coins associated with transactions.

12.14 Salt was a strategic necessity even where its routes are hard to reconstruct

Humans and livestock require salt, yet the alluvial plains did not possess equally distributed salt sources. Salt therefore had to move through exchange networks from production zones or redistribution centres. Direct archaeological identification of salt trade is difficult because the commodity dissolves and ordinary containers are rarely diagnostic. Historical reconstruction must therefore distinguish ecological necessity from specific route claims. We can infer that salt exchange was indispensable; we cannot assign every settlement to a named salt route without evidence.

12.15 Textiles were major commodities but leave a weak archaeological signature

Spindle whorls, needles, impressions and occasional fibre remains attest textile production, while literary sources repeatedly value cloth. Finished textiles, however, decay in humid alluvial settings and can travel without leaving trace. This creates a major imbalance: ceramic trade is archaeologically visible, textile trade often textual. Cotton and other fibres could move as raw material, yarn or finished cloth, and dyeing/finishing might occur at different stages. Because the evidence for specific early textiles of Mithila, Vaiśālī or Aṅga is fragmentary, the chapter avoids assigning later regional textile reputations to the first millennium BCE.

12.16 Beads, stone and metals reveal long-distance material circulation

Carnelian, agate, crystal, glass, copper and other non-local materials are among the clearest indicators that early settlements were connected beyond their immediate resource zones. The crucial question is whether a finished object was imported or made locally from imported raw material. Workshop waste, unfinished pieces, drilling debris and production tools can answer that question where preserved. Without such evidence, distribution proves movement but not its organisational form. The craft networks discussed in Chapter 11 therefore connect directly to commerce: production and trade were successive stages in one material chain.

12.17 NBPW distribution records connectivity but not a single commercial system

Northern Black Polished Ware is widely distributed across early historic northern India and beyond. Its fine fabric and distinctive surface make it useful for relative chronology and inter-site comparison. Some studies interpret its distribution as evidence of trade, and long-distance movement of vessels or technological knowledge is certainly plausible. But NBPW should not be treated as a map of one state-controlled market or as an automatic marker of elite ownership at every site. Vessels could circulate through trade, gifting, mobility or imitation. Its value for this chapter lies in demonstrating wide material connectivity during the urbanising centuries.

12.18 Punch-marked coins expanded transactional possibilities but did not replace non-monetary exchange

Silver and copper punch-marked coins occur across the Middle Ganga world and are closely associated with the early historic urban horizon. Coins made value more divisible, portable and countable and could

facilitate taxation, wages, credit settlement and trade. Yet coin presence does not mean every transaction was monetised. Barter, payments in kind, reciprocal obligations and commodity money could coexist. Hoards may represent savings or crisis deposition rather than ordinary market circulation. Vaiśālī's coin finds therefore demonstrate participation in monetised networks, but they do not provide a measurable “money supply” for the city.

12.19 Weights, measures and standardisation lowered transaction uncertainty

Commerce becomes easier when buyers and sellers share conventions for quantity and value. Archaeological weights, recurring vessel capacities and standardised coin forms can indicate attempts to make transactions comparable. But standardisation can emerge through craft practice and custom as well as state regulation. The absence of preserved weights at a particular site likewise cannot prove that measurement was absent. In a region where grain, metals and other divisible goods circulated, some agreed systems of counting and weighing were necessary; the historical question is how far they were local, regional or politically enforced.

12.20 Credit and debt extended exchange beyond immediate payment

Narrative and normative texts from early India refer to loans, debt, interest, sureties and wealthy financiers. Such practices are plausible in urban and mercantile settings because caravans and bulk trade require capital before sale. Yet local documentation for Vaiśālī and Campā is not an archive of contracts. Credit should therefore be treated as a systemic possibility strongly supported by wider textual evidence, not as a quantified local institution. The *ṣeṭṭhi* is especially relevant because concentrated wealth could finance commercial journeys, household enterprises or religious patronage, linking finance to both trade and public life.

Commercial roles formed networks rather than a single “merchant class”

Figure 46 — Commercial roles formed a network of producers, traders, financiers, carriers, markets and institutions rather than one homogeneous merchant class.

12.21 Guild terminology requires chronological discipline

The Sanskrit *śreṇī* and related terms are often translated as “guild,” but corporate organisation varied by craft, place and period. Later inscriptions provide clearer evidence for organised merchant and artisan bodies than the earliest urban phase. Early Buddhist literature contains collective occupational categories and

prominent set this, but this does not justify reconstructing a fully developed guild bureaucracy at every sixth- or fifth-century BCE city. “Guild” is therefore used sparingly here. Where evidence shows collective organisation it should be described specifically; where it does not, merchant networks, craft groups or occupational communities are safer terms.

12.22 Monasteries were consumers, recipients and nodes of mobility

Buddhist monasteries required food, cloth, medicines, building materials and repairs. Donations from merchants and householders linked religious institutions to urban and rural economies. Monasteries also hosted mobile monks and pilgrims, creating information networks that overlapped with commercial routes. Ray’s work on later early historic India demonstrates how strongly monastic and commercial landscapes could intersect, though her Satavahana evidence cannot be simply transferred to Vajji or Aṅga (Ray 1986, 2003). For Vaiśālī, the historically secure point is that religious institutions generated recurring demand and patronage within an already mobile urban society.

12.23 Women participated in exchange as producers, property holders, patrons and consumers

Chapter 9 showed that women’s economic roles are under-recorded when history looks only for formally titled merchants. Textile production, food processing, household provisioning, market purchasing and small-scale exchange could all involve women. Named women such as Ambapālī demonstrate that women could control substantial resources and convert them into religious patronage. This does not establish equal access to commercial authority, but it prevents the merchant economy from being reconstructed as exclusively male. Gender analysis must include both visible patronage and the less visible labour that produced marketable goods.

12.24 Transport depended on labour that elite merchant narratives obscure

Boats, carts, pack animals and caravans required boatmen, drivers, handlers, porters, animal keepers, repair workers and guides. These occupations are essential to commercial history even when texts foreground the wealthy merchant who owns the cargo. River crossings also required ferrymen and local knowledge. A realistic commercial network therefore includes many layers of labour, from cultivators producing surplus to transport workers moving it and retailers distributing it. Their invisibility in literary narratives should not be mistaken for economic insignificance.

12.25 Security, seasonality and transaction costs shaped route choice

Merchants chose routes not only by distance but by navigability, monsoon timing, flood conditions, robbery risk, ferry availability, political boundaries and access to fodder and water. Early texts frequently imagine dangerous journeys, which should be read as evidence that mobility carried real risk even if individual stories are literary. Political peace could lower transaction costs; warfare or river avulsion could redirect traffic. Commercial geography was therefore dynamic. A route on a map is only a corridor of possibility unless the season, transport technology and security conditions are considered.

12.26 Archaeology rarely identifies a “market” from one feature

Market archaeology requires clusters of evidence: access routes, open or built trading spaces, storage, weights, seals, coin concentrations, diverse goods, craft production and repeated occupation. In early Gangetic towns, later rebuilding and dense occupation can erase earlier market surfaces. Open-air periodic

markets are particularly elusive. The correct archaeological question is therefore not “where is the bazaar?” but “what combinations of evidence indicate repeated exchange?” This evidence-chain approach is represented in Figure 44 and is deliberately stricter than identifying every coin-bearing mound as a marketplace.

12.27 Oriup and Campā show the importance of the Bhagalpur corridor across long periods

Oriup, east of Campā, preserves earlier settlement evidence including Black-and-Red Ware and later cultural material (ASI 1966–67). Campā developed into a major early historic urban centre nearby. The two sites should not be collapsed into one continuous town, but together they show that the Bhagalpur-Ganga zone attracted settlement and exchange across multiple phases. Access to river transport, fertile alluvium and routes toward mineral and forest zones to the south and east would have made the corridor economically advantageous. The exact traffic volumes remain unknown, but the spatial setting supports repeated regional connectivity.

12.28 Nepal-side Mithila must be treated as a research frontier rather than filled by analogy

The early historic commercial archaeology of Nepal-side Mithila is less densely documented than the better-known sites of north Bihar and the central Ganga plain. Later Janakpur’s religious and market importance cannot be projected backward into the first millennium BCE without evidence. The appropriate method is comparative but explicit: northern routes through the Tarai and Himalayan foothills were possible, and trans-regional movement is historically plausible, but particular markets, merchant communities or commodity flows require archaeological or textual support. Absence of publication is not evidence of absence, yet it also cannot license invention.

Conceptual Ganga-Vajji-Aṅga exchange corridor

Schematic only: arrows indicate possible movement corridors, not measured traffic volumes or fixed political boundaries.

Figure 47 — Conceptual Ganga–Vajji–Aṅga exchange corridor; schematic, not a measured traffic map.

12.29 Eastern routes connected Aṅga to Bengal and eventually maritime worlds, but chronology matters

Campā's eastward position made it an important hinge between the Middle Ganga and the lower Ganga approaches. Later textual traditions remember voyages and merchants moving toward Suvaṇṇabhūmi, while

long-term archaeology demonstrates increasing eastern and maritime connectivity. Such evidence should not be compressed into a single sixth-century BCE “international trade route.” Riverine exchange toward Bengal could precede or differ from later organised maritime networks. Ray (2003) and Chakravarti (2020) show the importance of braided inland and maritime systems, but the chronology of each link must be established separately.

12.30 Conclusion: a networked economy without a timeless unified market

Early Mithila–Vajji–Anga participated in a networked economy generated by agrarian surplus, craft specialisation, mobile merchants, towns, rivers, roads, credit, coinage and institutional demand. Vaiśālī and Campā were major nodes, but their commercial worlds were not identical and their hinterlands shifted. Exchange operated at several scales—from household transactions and periodic rural markets to regional river corridors and selected long-distance journeys. The most important conclusion is methodological: connectivity does not prove political unity, imported goods do not prove local workshops, coins do not prove complete monetisation, and literary voyages do not yield measured trade statistics. Commercial history becomes stronger when each claim is matched to the evidence capable of supporting it.

Table 12.1 — Evidence for trade and the limits of inference

Evidence	What it can support	What it cannot prove alone	Regional relevance
Coins / hoards	Monetised transactions, storage of value, political or commercial circulation	Complete monetisation, prices, or exact transaction frequency	Vaiśālī and wider Middle Ganga networks
NBPW and other ceramics	Chronology, material connectivity, consumption patterns	A single trade organisation or state-controlled market	Vaiśālī, Campā, Chirand and associated sites
Beads / metals / shell	Movement of raw materials or finished goods	Where an object was manufactured without production evidence	Urban and craft sites across the region
Road / river geography	Possible corridors and transport advantages	Actual traffic volume or fixed routes in every season	Gandak–Ganga–Bhagalpur corridors
Buddhist / Jain narratives	Merchant categories, journeys, patronage and social attitudes	Measured trade statistics or exact contemporary route maps	Vesālī, Campā and wider eastern Gangetic world
Excavated storage / weights / seals	Repeated handling, measurement or administration of goods	A formal bazaar unless spatial context supports it	Potential market and institutional contexts

Chapter 13 — Vaishali as an Economic and Social Centre

Chapter argument. Vaiśālī should be understood neither as a literary city of splendour detached from archaeology nor as an excavated mound that can be interpreted without texts. Its historical importance lies in the convergence of a large early historic settlement, political institutions associated with the Licchavis and Vajji, a diversified material economy, regional routes, and unusually rich Buddhist and Jain memories. The evidence does not support a single census-like reconstruction of the city. Instead, it reveals an urban system in which residence, exchange, craft activity, political authority, religious institutions, agricultural provisioning and mobility were interdependent (Sinha and Roy 1969; Mishra 1962; Singh 2008).

13.1 An urban centre must be reconstructed from several evidence streams

The strongest reconstruction begins by keeping source types distinct. Excavation establishes structures, fortification phases, ceramics, coins, beads, terracottas, seals and other material remains. Buddhist and Jain texts preserve named people, institutions, journeys and social ideals, but they were transmitted for religious purposes rather than compiled as municipal surveys. Landscape history explains why routes, water, floodplain resources and agricultural hinterlands mattered. Finally, modern excavation reports and historical works are themselves products of particular scholarly moments. Yogendra Mishra's 1962 synthesis remains valuable for its collection of textual evidence on society, education and commerce, but its claims must be checked against archaeology and against the chronology of the sources it uses (Mishra 1962, 250–255; Sinha and Roy 1969).

Figure 48 — Vaiśālī must be reconstructed by converging evidence, not by a single source.

13.2 Vaiśālī was a distributed urban landscape rather than a single compact monument

The archaeological site identified with ancient Vaiśālī extends across multiple mounds and localities around Basarh and adjacent areas. The so-called fortified or civic core is only one component of this wider landscape. Excavation and exploration have revealed occupational zones, structural remains and religious complexes distributed across the area rather than concentrated in one surviving “city centre.” This matters

socially: different activities could occupy different sectors, and the archaeological visibility of one mound should not be mistaken for the full extent of urban life. UNESCO's tentative-list description likewise treats the ruins of Vaiśālī and nearby Kolhua as component properties with different archaeological remains and chronologies (Sinha and Roy 1969; UNESCO World Heritage Centre 2010).

13.3 The city is an archaeological palimpsest

Vaiśālī was occupied and reworked over many centuries. Early historic layers associated with NBPW and urban growth were followed by Mauryan monumentalisation and by later Śuṅga, Kuṣāṇa, Gupta and post-Gupta activity in different sectors. Consequently, the most visible ruins today are not necessarily the structures most relevant to the sixth- and fifth-century BCE social economy. A stupa, pillar, monastery or later brick complex can dominate the modern landscape while earlier deposits remain buried below, truncated by later construction or preserved elsewhere. Historical interpretation therefore has to separate the chronology of an object from the prestige of the tradition attached to it (Sinha and Roy 1969; UNESCO World Heritage Centre 2010).

13.4 NBPW belongs to a wider urban transformation, not to a uniquely Vaiśālīan culture

Northern Black Polished Ware is a major chronological and interregional marker in the archaeology of the middle Ganga plain. Its presence at Vaiśālī places the site within the broader early historic urban horizon discussed in Chapter 6. Fine ceramics, however, do not by themselves prove courtly luxury, a specific political constitution or a particular ethnic community. Their significance lies in association with settlement growth, diverse consumption, iron use, coinage, craft products and expanding networks across many sites. Vaiśālī's urbanity must therefore be demonstrated by an assemblage of evidence rather than by the presence of one diagnostic ware (Allchin et al. 1995; Chakrabarti 2009; Singh 2008).

13.5 Fortification records investment and boundary-making, not democratic equality

Ramparts and fortified sectors show collective investment in defence, enclosure and the organisation of space. They may also signal competition among early states and oligarchic polities. Yet fortification cannot tell us who voted, who was excluded from assemblies, or how resources for construction were mobilised. The familiar description of Vaiśālī as a “republic” belongs to a modern vocabulary used to translate ancient gaṇa-saṅgha institutions. Such terminology can be analytically useful only if it does not turn an elite political order into a claim of universal civic equality. The built boundary of the city and the social boundaries of participation are different historical problems (Sinha and Roy 1969; Singh 2008).

13.6 Floodplain geography connected Vaiśālī to movement and exchange

Vaiśālī's location in north Bihar placed it within a riverine and overland landscape linking the middle Ganga with the north. Rivers reduced the cost of moving bulky commodities, while roads and seasonal tracks linked towns, villages, ferry points and political centres. Mishra reconstructed routes from literary references, including connections between Vaiśālī and Rājagṛha and a northern route through settlements associated with Kosala and the Malla country. These route descriptions are useful for demonstrating remembered connectivity, but they cannot be converted into measured traffic volumes or fixed highways. Routes shifted with rivers, political conditions and seasons (Mishra 1962, 254–255; Chakravarti 2020).

13.7 The city depended on an agrarian hinterland

No large early historic settlement could survive from urban craft and trade alone. Grain, pulses, oilseeds, vegetables, fruit, dairy products, livestock, fuel and building materials had to move into the city from surrounding rural landscapes. Chapters 4 and 10 have shown that the middle Ganga economy was agriculturally diversified and strongly adapted to riverine seasonality. Vaiśālī's urban growth therefore presupposes networks of cultivators, herders, fishers, carriers and processors whose names rarely appear in elite narrative sources. The city's apparent wealth was ultimately tied to the productivity and risk management of households beyond the walls or core mounds (Sharma 1983; Singh 2008).

13.8 Urban provisioning was a logistical achievement

Food supply was not merely a background condition. A dense settlement created daily demand for cereals, cooked food, water, fodder, fuel and containers. Seasonal scarcity, flood disruption or route insecurity could quickly become urban problems. Archaeology rarely identifies a municipal grain system directly at Vaiśālī, so later administrative models should not be projected backward. What can be inferred is a recurring flow from rural producers and local markets into households, political establishments and religious communities. Storage facilities, pottery assemblages, transport technologies and market exchange formed parts of this provisioning system even when their institutional coordination cannot be reconstructed in detail (Sharma 1983; Allchin et al. 1995).

Figure 49 — Vaiśālī as an urban system linking civic core, neighbourhoods, institutions, hinterland and routes.

13.9 Markets linked household exchange to regional commerce

Chapter 12 distinguished household exchange, periodic markets, urban marketplaces and long-distance commercial networks. Vaiśālī likely participated at all these scales, but the archaeological signature of an open market can be slight. The city's material diversity—fine and coarse ceramics, ornaments, metals, beads, coins and other portable goods—is compatible with a vigorous exchange centre, especially when combined with its route position and textual reputation. Yet a concentration of traded objects does not identify the exact location of a bazaar, and literary praise of prosperity is not a price series. Market history has to be reconstructed from converging rather than singular indicators (Sinha and Roy 1969; Mishra 1962, 254–255).

13.10 Craft goods reveal consumption and specialisation, but not every workshop

Vaiśālī's excavated assemblages include categories associated with craft production and urban consumption: ceramics, terracottas, metal objects, beads, ornaments and seals. These finds indicate access to specialised products and to production networks. They do not automatically prove that every object was manufactured within the city. Chapter 11 established the stronger archaeological criteria for a workshop—raw materials, unfinished pieces, wasters, slag, crucibles, tools or production installations. Vaiśālī was certainly a major consumer and redistributor of craft goods; the precise balance between household production, local workshops and imported finished goods must remain object- and context-specific (Sinha and Roy 1969; Kenoyer, Vidale, and Bhan 1991).

13.11 Coins and seals illuminate transactions and administration without defining a modern market economy

Coins increased the portability and divisibility of value, while seals and sealings could participate in administration, ownership, authentication and institutional communication. Vaiśālī's long archaeological sequence has produced both monetary and sealing evidence. Their presence is important for the history of exchange and record-making, but neither category should be interpreted as proof that all transactions were monetised or that a fully bureaucratic municipality existed. Coin, credit, gift, payment in kind and reciprocal obligation could coexist. Seals may belong to different centuries and institutions, so each must be dated before being used to describe the early Vajjian city (Sinha and Roy 1969; Chakravarti 2020).

13.12 Water structures belonged to both practical and ritual landscapes

Tanks, wells and other water features served drinking, washing, craft activity, animals, ritual and institutional needs. The archaeological landscape around Vaiśālī and Kolhua includes tanks and later religious structures, while Buddhist traditions also attach significance to water places and groves. These remains should not be collapsed into a single early “municipal water system,” because their dates and functions vary. Their broader importance is that water management was indispensable in a populous alluvial settlement where monsoon excess and dry-season access posed different problems. Infrastructure was simultaneously technological, social and, in some contexts, sacred (UNESCO World Heritage Centre 2010; Sinha and Roy 1969).

13.13 Political assembly was one institution within a much larger urban society

The Vajjian conditions reported in the Mahāparinibbāna Sutta emphasise frequent assembly, collective meeting, respect for established practices, honour to elders, protection of women, reverence for shrines and support for arahants. These passages are among the most important textual windows onto the political culture associated with the Vajjians. They do not describe the whole population of Vaiśālī as members of one assembly. The city also contained householders, labourers, artisans, women, renunciants, visitors and dependent people whose political standing is not specified. Political history therefore has to be nested within social history rather than allowed to substitute for it (Walshe 1995, DN 16; Singh 2008).

13.14 Licchavi elites were visible because sources were interested in them

Buddhist texts repeatedly portray Licchavi nobles as conspicuous urban actors, sometimes emphasising their dress, vehicles, retinues, competitive prestige and collective action. Mishra used such passages to reconstruct an affluent and martial Licchavi elite and to discuss archery, elephant training, festivals and social

distinctions (Mishra 1962, 250–253). These descriptions are valuable evidence for elite ideals and literary memory, but they should not be treated as a representative sample of the city’s inhabitants. Archaeological inequality is more difficult to assign to named groups. The visibility of Licchavis in texts reflects both their political importance and the interests of the traditions that preserved them.

13.15 “Republic” is a political translation, not a description of social equality

Modern histories often celebrate Vaiśālī as an early republic or even as the world’s first democracy. The underlying evidence for collective political institutions is significant, but the modern labels can obscure oligarchic features and unequal access to power. Gaṇa and saṅgha polities could be organised through lineages or warrior elites while coexisting with servants, cultivators, artisans, merchants, women and other people without equivalent political voice. Volume II therefore uses “republic” only as a conventional shorthand when necessary and prefers the more precise language of Vajjian/Licchavi collective or oligarchic institutions. Social differentiation remains compatible with political deliberation among a restricted body (Singh 2008; Sharma 1983).

13.16 Householders and merchants connected domestic wealth to civic institutions

The Pāli category gahapati refers to a substantial householder and can carry implications of property, household authority and economic resources. Setṭhi and merchant terminology point to other forms of urban wealth and commercial specialisation. Vaiśālī’s social economy would have depended on such households for production, storage, patronage, credit and market demand. But these categories were not identical, and they should not be converted into modern occupational classes. Their importance lies in showing that urban power was not confined to formal political office: household resources could be mobilised through exchange, hospitality, gifts and religious donation (Liu 2022; Chakravarti 2020).

13.17 Ambapālī demonstrates the intersection of gender, property, prestige and patronage

The Mahāparinibbāna Sutta presents Ambapālī as a woman of sufficient status and resources to host the Buddha and his community and to donate her mango grove. The narrative famously contrasts her invitation with that of Licchavi nobles, making her an unusually visible non-Licchavi urban actor (Walshe 1995, DN 16). Her story should not be reduced either to romantic biography or to a claim that all women enjoyed comparable autonomy. It does, however, demonstrate that gendered urban institutions could coexist with significant female control of resources and public religious patronage. The grove itself also reveals how property on the urban edge could be converted into institutional space.

13.18 Women’s economic presence extended beyond exceptional named figures

Ambapālī survives because texts found her memorable; most women involved in the urban economy remain unnamed. Household provisioning, food processing, textile work, childcare, service, small-scale exchange and participation in family property were essential to city life even when archaeology cannot assign these activities by sex with certainty. Chapter 9 showed that early sources provide uneven windows onto female patrons, renunciants, mothers, servants and householders. Vaiśālī should therefore be analysed through both exceptional female agency and the largely invisible labour that sustained households and institutions. Absence of personal names is not evidence for absence from production or exchange (Liu 2022; Horner 1938–1966).

Figure 50 — The city's social economy depended on interacting groups, not a single civic elite.

13.19 Artisans, carriers and service workers formed the hidden infrastructure of urban prosperity

A prosperous city required potters, smiths, builders, carpenters, textile workers, food vendors, animal handlers, boatmen, cart drivers, porters, cleaners and many other workers. Some categories are visible through artefacts or texts; others leave little direct trace. Mishra's survey of Vajjian social conditions noted artisans and occupational groups, but his list was assembled from literary traditions and cannot be treated as an urban census (Mishra 1962, 250–251). The more defensible conclusion is structural: the material complexity of Vaiśālī could not have been produced or maintained without differentiated labour, much of it less visible than the activities of political and religious elites.

13.20 Religious institutions were economic consumers as well as sacred communities

Buddhist establishments required food, cloth, medicines, fuel, building materials, repair work and land or gardens. Donors moved resources from households and commercial fortunes into monastic use. Conversely, monasteries attracted visitors, teachers and pilgrims and could intensify demand around the urban fringe. This does not mean that a monastery functioned like a modern commercial corporation, nor should later epigraphic evidence be retrojected into the Buddha's lifetime. At Vaiśālī, the safest conclusion is that religious communities were embedded in the city's provisioning and patronage networks and therefore belonged to its social economy as well as its sacred history (Walshe 1995; Liu 2022).

13.21 Groves and monasteries show that the city extended beyond dense built-up space

Early Buddhist Vaiśālī is remembered through spaces such as the Mahāvana and Kūṭāgārasālā and through Ambapālī's mango grove. These names point to a city whose social geography included gardens, groves, monastic sites and routes beyond the densely occupied core. Archaeological remains at Kolhua include the later material history of Buddhist institutions in this landscape, with structures ranging from

Mauryan to post-Gupta periods (UNESCO World Heritage Centre 2010). The key urban point is not that every surviving structure dates to the Buddha, but that institutional and ritual spaces became durable parts of a wider Vaiśālī landscape.

13.22 Jain traditions make Vaiśālī part of a plural religious geography

Jain sources and later historical reconstructions connect Mahāvīra with the Vaiśālī–Videha region and preserve debates over Kundagrāma/Kundapura and related localities. Those traditions are crucial to the city’s religious history but require the same chronological discipline as Buddhist narratives. A remembered birthplace or lineage association does not by itself identify a modern village archaeologically. At the social level, however, the coexistence of Buddhist, Jain and Brahmanical actors within the wider region demonstrates that urban life was not organised around one exclusive religious community. Vaiśālī’s importance helped multiple traditions claim and remember it (Mishra 1962; Jaini 1979).

13.23 Education and debate were forms of urban social capital

Mishra assembled literary references to Licchavi education, archery and intellectual activity and argued that the region supported forms of training and learning (Mishra 1962, 253). Early Buddhist and Jain traditions likewise place teachers, renunciants, disputants and learned householders in urban and peri-urban settings. It would be anachronistic to imagine a university system comparable to later Nālandā. The better model is a plural ecology of learning: family training, elite martial education, religious instruction, memorisation, debate and itinerant teaching. Dense settlements increased the audience and patronage available to specialists in knowledge just as they did for artisans and merchants.

13.24 Traditions of epidemic and relief preserve social memory, not epidemiological statistics

The Ratana Sutta tradition associates Vesālī with severe affliction and ritual or religious intervention. Such narratives have often been retold as descriptions of plague, famine and civic crisis. They are important evidence for the remembered vulnerability of a dense settlement and for the social role attributed to religious specialists, but they cannot establish pathogen identity, mortality rates or a precise historical epidemic without independent evidence. The broader social-historical lesson is defensible: urban concentration depended on sanitation, water, food access and collective responses to crisis, and literary communities remembered Vaiśālī as a place where such vulnerability mattered (Khuddakapāṭha tradition; Liu 2022).

13.25 Festivals, display and consumption were part of the urban economy

Mishra’s discussion of Vajjian society cites literary descriptions of festivities, music, dress, ornaments and public display, especially among the Licchavis (Mishra 1962, 252–253). These passages cannot be treated as a calendar of municipal events or as evidence that every inhabitant shared elite consumption. They do, however, illuminate demand for textiles, jewellery, food, transport, musicianship and other services. Public prestige was economically productive: elite competition could sustain specialised makers and performers, while festivals brought people and commodities together. Consumption therefore belonged to the social economy rather than standing outside “serious” production and trade.

13.26 Visitors and pilgrims made population more fluid than a resident census would suggest

Vaiśālī's religious and political prominence drew monks, teachers, messengers, merchants, caravan travellers, delegations and later pilgrims. Such mobile populations consumed food and lodging, used roads and ferries, exchanged information and connected the city to other centres. Buddhist narratives of repeated journeys between Rājagṛha, Pāṭaligāma, Vaiśālī, Malla territories and other places are especially useful for reconstructing a world in which mobility was normal (Walshe 1995, DN 16). The texts do not allow traffic counts, but they show that the city's social composition was periodically enlarged by people who did not belong to its permanent resident population.

13.27 Regional connectivity helped make Vaiśālī important

Urban importance is relational. Vaiśālī occupied a position from which movement could connect the north Bihar plain to the Ganga and to routes toward Magadha, Kosala and the Himalayan foreland. Mishra's reconstruction of road and river connections is one early attempt to synthesise this geography from texts (Mishra 1962, 254–255). Modern economic history should add caution: routes were seasonal, political boundaries changed, and rivers migrated. Even so, the city's position within overlapping corridors helps explain why political assemblies, trade, religious institutions and mobile teachers could all concentrate there. Connectivity was a condition of urban centrality, not merely a consequence of it.

13.28 Kolhua and other satellite localities prevent a core-only history

The archaeological remains at Kolhua include the Aśokan pillar, stupas, a tank, monastic structures, shrines and other features representing a long Buddhist institutional history. UNESCO's tentative-list description dates the principal remains broadly from Mauryan through post-Gupta periods (UNESCO World Heritage Centre 2010). These later remains cannot simply be projected into the early Vajjian city, yet they are essential to understanding how the urban landscape expanded, was monumentalised and became a pilgrimage centre. A core-only model would miss this spatial and chronological transformation. Vaiśālī's history is the history of an urban region, not one fenced archaeological rectangle.

Broad sequence only: excavated sectors differ in chronology and preservation.

- 1** Antecedent settlement — site-specific pre-NBPW horizons
- 2** NBPW / early historic urban growth
- 3** Mauryan monumentalisation
- 4** Śuṅga-Kuṣāṇa reworking
- 5** Gupta and post-Gupta institutional landscape

Later monuments can dominate the visible landscape; earlier urban deposits may remain buried or disturbed.

Figure 51 — Vaiśālī is an archaeological palimpsest: visible monuments and early urban history are not the same layer.

13.29 The Second Buddhist Council belongs to the city's institutional afterlife

Buddhist tradition places the Second Council at Vesālī roughly a century after the Buddha's death, in connection with disputes over monastic practice. Whatever the exact historical reconstruction of the council, the tradition itself shows that Vaiśālī remained a major reference point in Buddhist institutional memory beyond the generation of the Buddha (Horner 1938–1966). This later importance should not be folded backward into the sixth or fifth century BCE without distinction. Instead, it demonstrates continuity of place-significance through changing institutions. The city that had been remembered as a Vajjian political and commercial centre was also reconstituted as a Buddhist institutional landscape.

13.30 Conclusion: centrality was produced by interdependence, not by one institution

Vaiśālī's economic and social centrality emerged from the interaction of a fertile hinterland, transport corridors, diversified craft consumption, markets, household wealth, political assembly, religious institutions, mobile populations and social differentiation. Archaeology confirms a substantial and long-lived urban settlement; texts illuminate actors and institutions that material remains cannot name; each source also has limits. The city was not socially equal because it possessed collective political institutions, nor was it prosperous simply because later texts praised its wealth. Its historical importance is better understood as a networked urban system whose political, economic, religious and domestic spheres continually depended upon one another. This framework prepares the comparison with Aṅga and Campā in Chapter 14.

Table 13.1 — Evidence for Vaiśālī as an economic and social centre, and limits of inference

Evidence	What it supports	What it cannot prove alone	Chapter use
Fortifications and structural remains	Urban investment, enclosure, repeated construction	Political equality, universal citizenship, exact population	Urban scale and spatial organisation
NBPW and ceramic assemblages	Chronology, consumption diversity, inter-site comparison	Ethnicity, one market system, local production of every vessel	Early historic urban horizon
Coins, seals and sealings	Transactions, administration, authentication, institutional activity	Complete monetisation or one bureaucracy	Exchange and record-making
Beads, metals, terracottas and ornaments	Access to specialised goods and wider material networks	Local workshop location without production debris	Consumption and craft connectivity
Buddhist and Jain texts	Named actors, journeys, institutions, social and religious memory	Census, exact chronology for every episode, archaeological identification	Social actors and institutional landscape
Route and floodplain geography	Potential corridors, hinterland relations, transport constraints	Measured traffic volumes or permanent roads	Regional centrality
Monasteries, groves, tanks and stupas	Long institutional and ritual history	That all surviving remains belong to the	Urban-region and palimpsest model

Evidence	What it supports	What it cannot prove alone	Chapter use
	across the wider site	Vajjian period	
Modern historiography	Source collection, interpretive debates, history of scholarship	Independent primary proof when based on the same literary traditions	Critical comparison and claim control

Chapter 14 — Anga and Champa

Chapter argument. Aṅga and its capital Campā must be reconstructed through a controlled combination of archaeology, early Buddhist and Jain textual traditions, river geography, and later historical testimony. Campā was not simply a literary “great city” or a modern place-name attached to Bhagalpur. Excavation near Nathnagar–Champanagar documents a fortified and repeatedly rebuilt settlement with Northern Black Polished Ware, ring-wells, coins, sealings, craft objects and structural remains. Texts add evidence for political incorporation, brahmanical endowment, religious debate, merchants, travellers and remembered long-distance exchange. The strongest history keeps these source types separate before asking where they converge.

14.1 Aṅga is a historical region, not a synonym for the modern Bhagalpur district

Early Sanskrit, Buddhist and Jain traditions use Aṅga as a regional and political name, but its boundaries shifted and cannot be mapped directly onto a modern district. The core association with the lower middle Ganga around Bhagalpur and Munger is strong, while claims about its maximum extent vary by source and period. For socio-economic history, the safer approach is to begin with securely associated places and routes rather than to draw a single timeless frontier. Campā was the principal urban focus of Aṅga in early historic literature, but the lives of cultivators, fishers, artisans and mobile traders extended beyond any capital’s walls. Modern Anga identity and Angika language history belong to later chapters and should not be projected backward as unchanged institutions.

ĀṆGA-CAMPĀ: DISTINCT EVIDENCE STREAMS

No single story, artefact, or modern place-name is sufficient by itself.

Figure 52 — Aṅga–Campā must be reconstructed from distinct evidence streams before they are combined.

14.2 The identification of ancient Campā with the Bhagalpur–Nathnagar landscape rests on converging evidence

The excavated “Champa mounds” lie near Nathnagar and Champanagar, west of central Bhagalpur. Archaeological Survey reports from 1968–69 onward recorded mud fortification, early pottery and later

structural phases in this zone (Indian Archaeology 1968–69: 4; 1970–71: 4–5). The resemblance between ancient and modern place-names is supportive but is not the whole case: the riverine setting, early historic occupation and literary geography strengthen the identification. At the same time, the exact limits of the ancient city remain a research question. A large archaeological landscape cannot be reduced to one mound, one modern neighbourhood, or one sacred enclosure.

14.3 Campā's river setting was an economic asset and an archaeological complication

Campā stood in a landscape shaped by the Ganga and subsidiary watercourses. River access lowered the cost of moving grain, timber, animals, pottery, stone and other bulky goods, and linked the city to both upstream and downstream settlements. Yet the same setting complicates archaeology: channels migrate, banks erode, low areas accumulate sediment and modern occupation obscures earlier surfaces. The city's riverine advantage therefore should not be turned into a claim that every commodity travelled by boat or that a stable ancient harbour has been located. What can be said securely is that Campā occupied an exceptionally favourable position for combining agricultural hinterland, river transport and eastern Ganga communication.

14.4 Fortification indicates collective investment, defence and boundary-making

Exploration and excavation revealed substantial mud ramparts. The 1970–71 season reported a second-phase rampart with a basal width of about fifteen metres and an extant height approaching five metres; later work identified an earlier rampart phase and associated brick and timber features (Indian Archaeology 1970–71: 4–5; 1971–72: 5). Such construction required organised labour and repeated maintenance. Fortification can signal insecurity, political competition, control over access, civic investment or elite authority, but it does not by itself reveal the constitutional form of the city. Nor should an excavated rampart be equated automatically with the walls described in later narrative texts.

CAMPĀ AS A RIVERINE URBAN SYSTEM — CONCEPTUAL, NOT A MEASURED MAP

Figure 53 — Campā as a riverine urban system: conceptual relationships among city, Ganga corridor, hinterland and markets.

14.5 Northern Black Polished Ware places Campā within the wider early historic urban horizon

Northern Black Polished Ware (NBPW) occurs in Campā's excavated deposits together with black-and-red, black and red wares. Its presence connects the site with the broader material transformation of the middle Ganga plain discussed in Chapter 6. NBPW is useful as a chronological and interregional marker, but it is not a badge of a single ethnic group, dynasty or "urban civilisation." At Campā it is significant because it occurs alongside fortification, ring-wells, structural remains, coins, beads, terracottas and other evidence of intensified occupation. The archaeological case for urbanism emerges from this bundle, not from one pottery type.

14.6 Excavation shows rebuilding rather than a single moment of urban foundation

The Champā excavations identified multiple rampart and construction phases. Work in 1972–73 distinguished structural periods associated with late NBPW, Kushan and Gupta horizons; later seasons exposed additional late-NBPW rooms, halls and drains (Indian Archaeology 1972–73: 6–7; 1975–76: 7–8). These sequences are crucial because literary traditions often imagine cities as if they were founded in a single act. Archaeology instead shows cumulative rebuilding, repair and reuse. The "city of Campā" was therefore a historical process. Its physical form changed even while the name and regional centrality could persist.

14.7 Ring-wells and drains document investment in dense settlement infrastructure

The 1970–71 excavations reported ring-wells within the habitation area, while later work encountered brick drains and substantial structural remains. Ring-wells can serve drainage, waste disposal, water management or other functions depending on context, so their interpretation must be specific rather than formulaic. At Campā their importance lies in demonstrating built investment below the scale of monumental fortification. Dense habitation creates recurring problems of water, refuse and circulation. Infrastructure therefore belongs to social and economic history: it required materials, specialised labour, maintenance and decisions about how space was organised.

14.8 Brick structures show differentiated interior space during the late-NBPW horizon

The 1975–76 season exposed late-NBPW structures comprising multiple rooms and a larger hall with brick-soling floors. Such architecture indicates planned interior spaces and durable construction, but room function cannot be assigned simply from shape. A hall need not be an assembly hall; a room need not be a shop. Artefact associations, access patterns and activity residues are required. The safest interpretation is that Campā contained substantial built environments in which domestic, administrative, commercial or craft functions may have overlapped. This is more informative than forcing every structure into a modern category.

SELECTED EXCAVATED HORIZONS AT CAMPĀ

schematic sequence — not an absolute dating chart

Lower deposits	Black-and-red and other wares
NBPW urban horizon	Mud ramparts · coins · ring-wells
Late NBPW structures	Brick floors · walls · rooms · drain
Kushan-Gupta phases	Successive rebuilding and occupation
Later historic / medieval	Long afterlife; later remains

Excavation shows sequence and rebuilding, not one precise founding date.

Figure 54 — Selected excavated horizons at Campā: sequence and rebuilding rather than a single founding moment.

14.9 Craft evidence reveals a diversified material economy

Excavation yielded terracotta plaques and figurines, stone and semi-precious-stone beads, bone points, iron and copper objects, ivory pieces, toy carts, seals and moulds. These finds reveal a city in which specialised objects circulated and multiple craft traditions were represented. They do not prove that every item was manufactured locally. Chapter 11 established the distinction between object presence and workshop evidence. At Campā that distinction is especially important because a commercial centre could import finished goods while also supporting local specialists. The archaeological question is therefore not “Was Campā a craft city?” but which stages of which production chains can be demonstrated on site.

14.10 Jewellery moulds provide unusually strong evidence for local manufacture

Among Campā’s most informative finds are stone moulds associated with jewellery production. The 1974–75 review noted moulds for ornaments and argued, on the basis of repeated discoveries across phases, that jewellery manufacture continued into the Gupta period (Indian Archaeology 1974–75: 8–9). Moulds move the inference beyond mere consumption because they represent a production tool. Even here, scale remains uncertain: the evidence does not tell us the number of workshops, their ownership, or whether artisans worked independently, for households, or under elite patronage. It does, however, support a durable tradition of skilled manufacture.

14.11 Iron, copper, bone and ivory show technological pluralism rather than a single “metal age”

Campā’s assemblage combines iron tools and weapons, copper objects and coins, bone implements and ivory artefacts. This mixture is typical of complex early historic technology. New materials did not simply replace older ones. Bone and ivory remained valuable for points, ornaments, dice and fine objects; copper retained roles in ornaments, vessels and currency; iron expanded possibilities in tools, construction and weaponry. The social history of technology lies in access to raw materials, skill, repair and market demand.

Material choice depended on cost, function, status and availability, not on a linear ladder from “primitive” to “advanced.”

14.12 Coins and sealings show portable value and administrative communication, not a fully monetised economy

Cast copper coins and terracotta sealings occur in Campā’s excavated contexts. Coins made value more portable and divisible, while sealings could be used in administration, storage, ownership or authentication. Their presence strengthens the picture of an urban centre with transactions and institutional communication. It does not mean that taxes, wages and market exchange were all paid in coin. Grain, labour obligations, gifts, credit and barter could coexist with money. The proportion of monetary to non-monetary exchange cannot be calculated from the survival of coins alone.

14.13 Campā depended on a productive rural hinterland

A fortified city of this scale required regular inflows of grain, pulses, oil, vegetables, dairy products, livestock, fodder, firewood, timber and clay. The Ganga plain around Campā offered fertile agricultural land but also flood risk and seasonal variation. Urban demand could encourage specialised production and market-oriented surplus, yet the archaeology does not permit a precise reconstruction of crop acreage, tenancy or prices. The key socio-economic point is interdependence: urban craft specialists and religious communities depended on rural producers, while villages gained access to manufactured goods, markets, credit and political institutions through the city.

14.14 Campā’s market function emerged from location, population and institutional demand

An urban market is not merely a named bazaar. It is a recurring concentration of buyers, sellers, carriers, storage, information and rules. Campā’s position on the Ganga, its fortification, craft assemblage, coins and textual reputation as a major city together make a strong case for substantial exchange activity. Religious visitors and political officials added demand to resident consumption. Periodic rural markets, neighbourhood exchange and larger urban marketplaces could all coexist. The evidence does not allow their exact locations to be mapped inside the ancient city.

CAMPĀ'S ECONOMY: RECIPROCAL FLOWS

goods · labour · value · patronage · information

Interdependence does not imply a fully monetised or centrally administered economy.

Figure 55 — Campā's economy depended on reciprocal flows among rural producers, urban households, merchants, crafts and institutions.

14.15 Buddhist texts preserve a vivid image of Campā as a city of householders, brahmins and visitors

The *Soṇadaṇḍa Sutta* (DN 4) places the Buddha at Campā on the bank of the Gaggārā lotus pond and describes the brahmin *Soṇadaṇḍa* living there on a royal grant from Bimbisāra. Other canonical passages remember the Buddha, *Sāriputta*, *Vaṅḡsa* and lay followers at Campā. These texts are valuable because they situate religious debate inside a socially differentiated urban setting of brahmins, householders, rulers, monks and lay communities. They are not censuses. Named figures survive because the texts had doctrinal and narrative reasons to remember them.

14.16 Literary memories of merchants and *Suvaṇṇabhūmi* should be used as evidence for imagined commercial horizons, not shipping statistics

Later Buddhist narrative traditions associate Campā's merchants with voyages toward *Suvaṇṇabhūmi*. Such stories are often cited to call Campā a maritime port. The geographical possibility of moving down the Ganga toward the sea is real, but a *Jātaka* is not a harbour ledger. The strongest formulation is therefore that eastern Indian literary memory associated Campā with ambitious long-distance trade and waterborne mobility. Direct archaeological proof of a specific Campā-to-Southeast-Asia shipping route in the early historic period is much thinner. The chapter keeps the literary horizon and the material evidence in dialogue without collapsing them.

14.17 The *Soṇadaṇḍa* endowment illuminates political economy after Aṅga's incorporation into Magadha

DN 4 states that *Soṇadaṇḍa* enjoyed Campā as a royal grant from King Bimbisāra, described as productive in grain, water, wood and living resources. Whatever the precise institutional form behind the Pāli description, the passage is important because it links political conquest, revenue assignment, agrarian

resources and brahmanical prestige. A city and its hinterland could be embedded in relationships of royal patronage as well as market exchange. The text should not be treated as a cadastral document, but it offers a rare window into how political control could be expressed economically after the loss of Aṅga's independence.

14.18 Gaggarā's lotus pond represents public landscape, memory and patronage

Buddhist tradition repeatedly locates the Buddha beside the Gaggarā-pokkharāṇī, a lotus pond associated with Queen Gaggarā and a grove of campaka trees. Whether every topographical detail can be matched to a modern waterbody is less important than the urban function implied by the tradition. Tanks and groves could supply water, shade, leisure, gathering space and locations for teachers outside dense habitation. A remembered royal woman as patron also introduces gender into public landscape. The pond is therefore useful socio-cultural evidence, provided literary memory is not mistaken for an excavated plan.

14.19 Campā was a node in the circulation of teachers and ideas

Canonical texts place multiple discourses and monastic episodes at Campā, including the Soṇadaṇḍa and Kandaraka settings and Vinaya material. Such repetition suggests that the city occupied a recognised position within routes of teaching and travel. Religious mobility depended on the same infrastructures as commerce: roads, ferries, food supply, lodging and donor households. Intellectual history is therefore inseparable from economic history. A city able to host large groups of mendicants and audiences needed surplus and social organisation, even though texts naturally emphasise doctrine rather than provisioning.

14.20 Vinaya traditions make Campā part of the institutional geography of the Buddhist Saṅgha

The Vinaya preserves episodes and formal decisions associated with Campā. These traditions show that the city was not merely a place where sermons happened; it also became part of the remembered institutional geography in which questions of monastic procedure were discussed and regulated. The historicity of every narrative detail must be evaluated separately, but the cumulative evidence marks Campā as an important eastern centre in Buddhist memory. Institutional gatherings also had material consequences: visiting monks required food, cloth, medicine and temporary or permanent accommodation.

14.21 Jain traditions add a different sacred map of Campā

Jain traditions connect Campā with Tīrthaṅkara memory, especially Vāsupūjya, and with the itineraries of later teachers. Modern Champapuri remains a major Jain sacred centre. These traditions are essential to the long cultural history of the place, but they have their own textual chronologies and theological purposes. They should not be used mechanically to date excavated layers. What they demonstrate securely is the durability of Campā/Champāpuri as a remembered sacred landscape across communities and centuries.

14.22 The city's prosperity depended on labour that elite texts rarely name

Rampart building, brick manufacture, transport, pottery production, food processing, cleaning, animal care, ferrying, carting and craft work required large amounts of labour. Elite and religious texts tend to preserve kings, brahmins, merchants and teachers more readily than porters, builders or dependent workers. Archaeology partly corrects that imbalance because walls, drains, tools and production debris embody work even when workers' names are lost. A socio-economic history of Campā must therefore treat labour as central rather than as background scenery.

14.23 Women participated in the urban economy even when the evidence names few of them

Women appear most visibly in textual memory as patrons, householders, courtesans, queens or renunciants, while archaeology rarely permits sexing everyday work. Yet the functioning of an early historic city depended on food preparation, textile production, childcare, retail, service, ritual and household management, many of which involved women. Queen Gaggārā's remembered association with a public pond is one unusual example of female patronage. The chapter avoids assigning every spindle whorl or domestic artefact to women, but it also avoids reproducing the textual silence as if women were economically absent.

14.24 Wealth, ritual prestige, political rank and labour status intersected without forming one simple hierarchy

Campā's texts and archaeology reveal several axes of inequality. Soṇadaṇḍa represents brahmanical prestige combined with a royal economic grant; merchants could possess substantial wealth without political sovereignty; rulers and officials controlled resources; artisans possessed specialised skills; dependent labourers had less autonomy. Gender and life stage further shaped access to property and institutions. These dimensions did not necessarily coincide. The city therefore reinforces the argument of Chapter 8: early social differentiation should not be reduced to a fully fixed later caste map.

14.25 Aṅga's incorporation into Magadha changed sovereignty without erasing Campā's urban importance

Political traditions remember rivalry between Aṅga and Magadha and the eventual annexation of Aṅga by Bimbisāra. By the setting of DN 4, Bimbisāra is clearly represented as exercising authority at Campā. Conquest altered fiscal and political relations, but cities do not disappear simply because sovereignty changes. Campā remained important enough to appear among the major cities remembered in Buddhist literature. This continuity is economically plausible: a conqueror had reason to preserve and appropriate a productive city, its revenue, routes and institutions.

14.26 Urban continuity after conquest was compatible with repeated physical transformation

Archaeological phases at Campā extend well beyond the early NBPW horizon into Kushan, Gupta and later periods. This long sequence warns against telling the city's history only through the sixth–fifth centuries BCE. The meaning of “Campā” changed as new buildings, religious communities and political systems appeared. At the same time, reuse of location and infrastructure could preserve regional centrality. Historical continuity here means repeated occupation and memory, not an unchanged urban form or social order.

14.27 Xuanzang's seventh-century description belongs to Campā's later afterlife, not to the Buddha's city

The Chinese pilgrim Xuanzang described the country and capital of Champā many centuries after the early historic period, noting a fertile landscape and Buddhist establishments. His account is valuable for the long history of the region and for showing that the place remained legible as an important centre. It cannot be projected backward to reconstruct the size, monastery count or street plan of Campā in the Buddha's lifetime. The chronological gap is itself historically useful: it demonstrates how sacred and urban geographies were reworked over time.

14.28 Later centres such as Vikramaśīlā belong to the same broad eastern Ganga corridor but not to early Campā's urban system

The Bhagalpur region later contained major institutions such as Vikramaśīlā. Their presence confirms the long strategic importance of the eastern Ganga corridor, but they should not be folded into an “ancient Campā complex” spanning a millennium. Each site has its own chronology, patronage and economic base. Regional history becomes stronger when connections are traced without erasing temporal difference. The river corridor persisted; the institutions occupying it changed.

14.29 Campā's relation to Mithilā was one of connectivity across the Ganga world, not territorial identity

A Jātaka tradition gives a conventional distance between Campā and Mithilā, while later geographical writing often places Mithilā primarily north of the Ganga and Aṅga to the south and east. Such evidence is useful for reconstructing perceived spatial relationships but not for drawing fixed modern-style borders. The two regions participated in overlapping exchange, pilgrimage and political networks. This volume therefore treats Mithilā and Aṅga as connected historical regions, not as interchangeable territories or as parts of a single timeless polity.

14.30 Conclusion: Campā was a fortified river city whose centrality was repeatedly remade

The strongest reconstruction of Campā rests on convergence. Archaeology documents fortification, NBPW occupation, ring-wells, rooms, drains, coins, sealings and specialised craft evidence. Buddhist texts remember a major city of brahmins, householders, rulers, teachers and travellers beside the Gaggara pond; Jain traditions preserve another sacred geography; later pilgrims document the site's continuing religious importance. River location linked Campā to hinterland production and wider routes. None of these sources alone proves the whole city. Together, critically separated and then recombined, they reveal Aṅga's capital as a durable socio-economic node whose political sovereignty, built form and cultural meanings changed over time.

Table 14.1 — Evidence for Aṅga and Campā, and limits of inference

Evidence	What it supports	What it does not prove alone	Key references
Mud ramparts and structural phases	Fortification, organised construction, rebuilding and dense occupation	Exact political constitution or identity of builders	IAR 1968–69; 1970–71; 1971–72
NBPW and associated pottery	Early historic chronology and interregional material links	A single ethnicity, dynasty or exact foundation date	IAR 1968–69; 1971–72; Singh 2008
Ring-wells, drains, rooms and halls	Investment in urban infrastructure and durable built space	Specific room functions without activity evidence	IAR 1970–71; 1975–76

Chapter 15 — Early money and monetisation

Chapter argument. Early money in Mithilā, Vajji and Aṅga should be reconstructed as a layered history of measurement, portable value, coin manufacture, circulation, credit and institutional payment rather than as a simple transition from barter to cash. Silver punch-marked and copper coins widened the possibilities of exchange, taxation and saving, but their presence does not prove that all transactions were monetised. This chapter therefore combines numismatic evidence with archaeological context, urban systems, textual vocabulary and fiscal institutions while preserving the limits of each source. A key regional anchor is the Gorho Ghat hoard of fifty-eight silver punch-marked coins from the wider Bhagalpur–Aṅga corridor, set beside the urban monetary evidence of Vaiśālī and Campā.

15.1 Monetisation is not synonymous with the appearance of coins

The history of money begins before a society becomes fully or uniformly monetised. Money can function as a unit of account, a means of payment, a medium of exchange and a store of value, and these functions need not develop together. A silver piece accepted by weight may settle a large payment even where daily food exchange remains in kind. A coin may be used for taxes or merchant settlement while wages are partly paid in grain. Chapter 12 therefore treated punch-marked coins as one component of expanding exchange; this chapter asks the narrower and more difficult question of how far monetary practices penetrated the societies of Mithilā, Vajji and Aṅga. The central methodological rule is that coin finds prove the presence of portable monetary objects, not a universal cash economy. Monetisation must be reconstructed from the density, contexts and social uses of monetary evidence rather than declared from the first occurrence of coinage.

15.2 Before coinage, value could already be measured, transferred and owed

Coinage did not create exchange, debt or valuation from nothing. Agrarian households could reckon obligations in grain, livestock, labour days, metal, cloth or other customary units. Weighed metal could serve as a high-value transferable resource without being stamped as a coin, and standard weights could make such transfers more comparable. Gifts, bridewealth, fines, tribute, wages, loans and commercial credit all require ways of evaluating claims even when settlement is not made in minted currency. For early north India the evidence is uneven, but the analytical point is secure: a transition from “barter” to “money” is too simple. Several media and accounting conventions could coexist. The emergence of punch-marked coinage should therefore be understood as a new technology of standardised portable value inserted into older systems of measurement, obligation and exchange, not as the sudden birth of an economy.

15.3 Five evidence streams are needed to reconstruct early money

No single source can establish the extent of monetisation. Archaeological context tells us where coins, weights and hoards were deposited. Numismatic analysis examines metal, weight, manufacture, punch combinations and wear. Settlement archaeology identifies markets, craft zones, storage, roads and river access that made repeated exchange possible. Texts preserve monetary vocabulary, fines, prices, salaries and fiscal prescriptions, but their date and genre must be controlled. Institutional evidence concerns treasuries, taxation, merchant credit and official checking. Figure 56 formalises this separation. The strongest claim is made only when several streams converge. A coin from a disturbed layer cannot date the layer securely; a word such as *paṇa* in a normative text does not prove that every household used coins; and a hoard reveals accumulation but not the number of market transactions that produced it.

EARLY MONEY: DISTINCT EVIDENCE STREAMS

Figure 56 — Early money and monetisation: distinct evidence streams must be combined before historical inference.

15.4 The beginning of Indian coinage remains a chronological problem, not a single secure date

Punch-marked silver belongs to the formative early historic centuries of northern South Asia, but the exact beginning of the series has long been debated. Older scholarship often placed the first issues as early as the sixth century BCE, while later typological and archaeological studies have refined particular regional sequences and sometimes preferred more cautious chronologies. The safest formulation for this volume is that punch-marked money was established in the middle Ganga world during the later first millennium BCE and expanded substantially before and during the Mauryan period. Individual series must be dated by hoard composition, stratified context, overstriking, metrology and typological sequence rather than by attaching every anonymous punch-marked piece to a named ruler. This caution is especially necessary in Mithilā–Vajji–Aṅga, where many finds entered museums through hoards or chance discoveries rather than controlled excavation.

15.5 Punch-marked silver was manufactured by weight and repeated stamping rather than by a single engraved die

The characteristic technology of early punch-marked silver differs from later two-sided die-struck coinage. A piece of silver was cut or otherwise prepared, adjusted toward a weight standard, and marked with separate punches. The resulting flans can be irregular in outline because conformity of weight mattered more than perfect circularity. Several symbols could be impressed on one face and smaller marks could be added during circulation or checking. Mukherjee and Lee's study of Indian minting technology and the classifications of Allan, Agrawal and Rai, Rajgor, and Gupta and Hardaker show why manufacture itself is historical evidence: it implies access to silver, tools, skilled handling, standards and trusted marks. Figure 57 presents the object as a process from metal supply to manufacture, circulation, checking and eventual loss or hoard deposition.

PUNCH-MARKED SILVER: A MATERIAL PROCESS

Figure 57 — A punch-marked silver coin as a material process from metal supply to deposition.

15.6 Symbols are evidence of control and classification, but their meanings cannot simply be read as names

Punch-marked coins are usually anepigraphic. Their suns, geometric forms, animals, trees, hills and composite devices do not normally spell out an issuing ruler in the way a later legend can. Numismatists therefore classify series through recurring combinations, punch order, weight, fabric, provenance and hoard association. Some symbols or symbol groups have been linked to political authorities or chronological series with varying degrees of confidence, but a direct equation between a symbol and a named dynasty is not automatically warranted. The history of early money must consequently distinguish secure physical observations from interpretive attribution. A repeated punch may demonstrate a shared monetary convention even when the person or institution that authorised it remains uncertain. This anonymity is itself important: acceptance could depend on standard, recognisable marks and testing practices rather than on a royal portrait or written name.

15.7 Weight standards made pieces comparable, but actual coins vary

The Magadha–Maurya *kārṣāpaṇa* series is commonly associated with a standard around thirty-two rattis, approximately 3.4 grams, and museum specimens frequently cluster near this value. Yet surviving coins do not all weigh exactly the same. Cutting, adjustment, alloy composition, wear, corrosion, clipping and later handling create variation, while earlier or regional series can follow different standards. Metrology is therefore powerful when applied statistically to groups, not when used to force every isolated piece into a predetermined denomination. A standard is a social convention expressed through tolerances. In practice, users could combine recognition of type with weighing and testing. For the historian, the important development is not numerical perfection but the creation of repeatable expectations that allowed strangers, officials and merchants to compare pieces of metal more quickly than if every payment began as an entirely unstandardised bullion transaction.

15.8 Repeated checking marks suggest that trust was maintained during circulation

Some punch-marked coins carry subsidiary or reverse marks interpreted in numismatic literature as later checking, bankers' or control marks. Their precise institutional attribution can be uncertain, but the material

fact of repeated marking is significant. Money does not circulate through state proclamation alone; users must be willing to accept the object. Where intrinsic metal value mattered, weight, touch, visual inspection and additional marks could help sustain confidence. Rechecking also shows that a coin had a biography after manufacture. The same silver piece might pass through many hands, be tested more than once and remain acceptable across political changes. This complicates attempts to derive political boundaries directly from coin distribution. A coin can outlive its issuer, cross a frontier, be revalidated locally or enter a hoard far from its point of manufacture.

15.9 Hoards are records of accumulation and interruption, not frozen samples of ordinary markets

A hoard is one of the richest but most easily misunderstood forms of monetary evidence. It may represent savings, a merchant's working capital, an institutional reserve, ritual deposition, concealed wealth during danger or a stock of metal intended for remelting. The date of burial is later than or equal to the youngest object in the deposit, but older coins may have circulated for decades. Hoard composition is therefore excellent for studying which types could coexist and for constructing relative sequences, yet it does not reveal the frequency of small retail transactions. Large silver hoards may overrepresent high-value storage, while low-value copper used repeatedly in markets is more likely to be lost singly. Chapter 15 consequently treats hoards and stray finds as different archaeological behaviours rather than pooling them into one undifferentiated count of "money."

15.10 The Gorho Ghat hoard provides a concrete monetary anchor for the Āṅga–Bhagalpur zone

In 1917 fifty-eight silver punch-marked coins were found at Gorho Ghat, north of the Ganga in what was then Bhagalpur District. E. H. C. Walsh published a detailed examination of the find in the *Journal of the Bihar and Orissa Research Society* in 1919 and later used it, together with the Patna find, in his 1924 synthesis on Indian punch-marked coins. This is exceptionally useful for the present regional history because it places a substantial body of early silver currency in the wider Bhagalpur–Āṅga landscape rather than relying only on general statements about "Gangetic coinage." The hoard demonstrates that punch-marked silver could be accumulated in this corridor. It does not identify the occupation of the depositor, the source of the silver, the market in which the coins were acquired, or the percentage of local transactions that were monetised.

15.11 Vaiśālī connects monetary finds with a major excavated urban sequence

Vaiśālī is important because coins occur within a broader archaeological record of fortification, ceramics, beads, terracottas, metalwork, seals and dense occupation. Sinha and Roy's excavations, discussed in Chapter 13, place monetary objects inside an urban assemblage rather than treating them as isolated collectibles. This association makes monetised exchange plausible in several settings: market transactions, payments to artisans or carriers, institutional donations, tax collection, savings and merchant settlement. Yet even here the ratio between coin and non-coin exchange cannot be calculated. Perishable commodities and credit leave weaker archaeological traces than metal currency. Vaiśālī therefore shows what coinage looks like when embedded in an urban economy, but it should not be converted into the claim that all residents regularly handled silver *kārṣāṇas* or that rural communities in its hinterland were monetised to the same degree.

15.12 Campā adds copper money and urban administration to the eastern corridor

Chapter 14 noted cast copper coins and sealings from the excavated Campā sequence near Nathnagar–Champanagar. These finds broaden the monetary picture beyond silver punch-marked currency. Copper could support lower-value transactions for which a full silver unit was inconvenient, while cast coinage represents a manufacturing tradition different from punch-marked silver. The coexistence of coins with sealings, craft production, ring-wells, substantial structures and the Ganga route is consistent with repeated commercial and administrative activity. It remains unsafe to identify every copper coin as a state wage payment or every sealing as a tax receipt. What Campā contributes is evidence for diversified instruments of exchange and authentication within a major urban centre. The monetary history of Aṅga is therefore not reducible to a single silver standard or to the Gorho Ghat hoard alone.

15.13 Pāṭaliputra, Vaiśālī, Gorho Ghat and Campā belong to a connected corridor without forming one homogeneous monetary zone

The Ganga and its tributary routes linked political capitals, river crossings, markets and agrarian hinterlands. Punch-marked silver from Patna and Gorho Ghat, urban coin finds at Vaiśālī and copper currency at Campā can therefore be studied as parts of a connected middle and eastern Ganga world. Figure 58 is deliberately conceptual rather than a measured map. Connectivity does not mean identical monetary practice. One centre may have had denser silver circulation, another greater use of copper, and rural zones may have relied more heavily on grain, labour obligations or credit. Political annexation likewise need not immediately standardise every local transaction. The correct historical scale is a network of overlapping monetary practices whose intensity varied by settlement type, transaction size, access to metal and institutional demand.

SELECTED MONETARY EVIDENCE — GANGA CORRIDOR

Figure 58 — Selected monetary evidence in the middle and eastern Ganga corridor; conceptual, not a measured map.

15.14 Copper coinage matters because monetisation includes small payments

Histories built only from silver risk mistaking the currency of larger payments for the whole monetary economy. Uninscribed cast copper and punch-marked copper issues are well represented in catalogues of early Indian coinage and occur at many early historic sites. Their lower intrinsic value made copper more suitable for modest transactions, although denomination and purchasing power cannot be reconstructed simply from metal. Copper also corroded differently from silver and could be discarded more readily,

affecting archaeological visibility. A society in which silver circulated among merchants, officials and wealthy households but copper entered local markets would have a broader monetary reach than silver hoards alone suggest. Conversely, a few copper finds do not prove ubiquitous petty cash. The social depth of monetisation must be assessed from context, quantity, wear and association with settlement activity.

15.15 Silver and copper served different scales of value while older media continued beside them

Early monetary systems were plural. Silver could concentrate substantial value in a portable form; copper could facilitate smaller payments; weighed metal remained meaningful; and grain, cloth, livestock, labour and credit continued to settle obligations. This is not evidence of an incomplete transition waiting to become “modern.” It is a functioning mixed economy in which different instruments were suited to different transactions. A farmer might owe produce to a landlord, receive coin for surplus grain in a market and purchase salt on credit from an itinerant trader. A merchant might settle a large account in silver yet pay carriers partly in food. Figure 59 represents monetisation as a spectrum rather than an on/off condition. The historical task is to identify where monetary instruments reduced transaction costs and where social relations continued to organise exchange without coin.

Figure 59 — Monetisation as a spectrum of overlapping practices rather than an on/off condition.

15.16 Weights, measures and coinage belong to the same history of comparability

Money works best when value can be compared. The use of weight standards for silver, measures for grain and recurring denominations for coins all reduce uncertainty between parties who may not know one another personally. Standardisation does not require a single central authority in every case; merchants, guild-like groups, markets and political administrations can all reinforce conventions. Conversely, a royal prescription in a text does not prove perfect compliance in practice. Archaeological weights, when securely contextualised, should therefore be studied together with coins and commercial spaces. The broader transformation is the creation of interoperable measures: a merchant can calculate how much metal, grain or commodity is owed and translate one claim into another. This capacity is a foundation for taxation, wages, credit and larger market networks even when actual payment media remain diverse.

15.17 Terms such as paṇa and kārṣāpaṇa are valuable only when genre and date are controlled

Pāli, Sanskrit and Prakrit sources use monetary terms including kahāpaṇa or kārṣāpaṇa and paṇa, but a textual word is not automatically an excavated coin type. Terms can refer to units of account, conventional values or specific pieces, and their meaning may shift over time. Buddhist narrative and disciplinary literature often preserves prices, donations, fines or monetary comparisons because such values mattered to householders and institutions; later redaction, however, can carry contemporary monetary language into stories set earlier. Normative Sanskrit texts likewise organise elaborate systems of value that may describe ideals rather than observed market practice. Chapter 15 therefore uses textual monetary vocabulary to reconstruct the social intelligibility of money, while archaeology and numismatics establish the material forms in circulation.

15.18 Pāṇini's monetary vocabulary is evidence for conceptualised struck money, not a complete monetary census

Classical grammatical discussions are important because Pāṇini's Aṣṭādhyāyī includes technical vocabulary connected with rūpa and struck or marked objects, a point noted in modern scholarship on the Arthaśāstra and coinage. Such evidence supports the existence of a developed language for monetary and marked value in early northern India. It should not be overextended into a precise map of coin use in Mithilā, Vaiśālī or Campā. The date of a grammatical rule, the geographic range of the linguistic examples and the archaeological date of a particular coin series are separate questions. Linguistic evidence is strongest when it demonstrates that coined or marked value had become conceptually familiar; it is weaker when asked to prove the quantity of money in circulation or the social class of users.

15.19 The Arthaśāstra describes an advanced monetary administration, but the text is composite

The Arthaśāstra contains detailed discussions of treasury, revenue, wages, fines, minting, testing and officials associated with currency. Patrick Olivelle's study of its compositional history emphasises that the work reached its surviving form through layered transmission rather than being a verbatim administrative manual from one moment in the reign of Chandragupta Maurya. Its monetary prescriptions are therefore indispensable evidence for the developed political economy of early India, but they cannot simply be projected backward to the age of Bimbisāra or onto every republican and regional polity. The text is most useful comparatively: it shows the kinds of problems that a monetised state sought to control—metal quality, authorised manufacture, revenue assessment, salaries and fraud. Archaeological contexts must determine where and when such administrative capacities can be inferred in the regions studied here.

15.20 Taxes, fines and wages could accelerate demand for money without eliminating payment in kind

States create monetary demand when obligations are assessed or collected in monetary units. Salaries and fines expressed in paṇas similarly make coin useful to officials, soldiers, litigants and suppliers. Yet early fiscal systems could combine cash and kind. Grain taxes, corvée labour, requisitioned animals and in-kind provisioning remain compatible with a treasury that also receives silver. The degree of fiscal monetisation may vary between cities, frontier zones and agrarian villages. This distinction prevents a common circular argument: coins are found, therefore the state taxed everyone in cash; the state is assumed to tax in cash, therefore the coins must be state fiscal issues. The evidence instead supports a more limited claim that

expanding states and cities created recurring contexts in which portable standardised value was advantageous, strengthening the demand for coin alongside older forms of extraction.

15.21 Merchant exchange and credit could expand monetisation without requiring coin at every stage

Merchants benefit from money because it allows unlike goods to be priced in a common unit, reduces the bulk of carrying commodities for barter and makes accounts easier to settle across distance. But commercial sophistication is not measured by the proportion of transactions paid immediately in coin. Credit can reduce the need to move cash; partnership arrangements can pool capital; advances can finance production; and debts can be netted against later deliveries. Chakravarti's work on early Indian trade stresses the agrarian and everyday material basis of commerce, not only luxury traffic. For the Ganga corridor, the combination of urban centres, river transport, craft production and coinage suggests increasing capacity for monetised settlement, while credit and commodity payments probably remained integral. Money and credit should therefore be analysed as complementary rather than rival institutions.

15.22 Urbanisation and monetisation reinforced one another but neither mechanically caused the other

Early historic urbanism in the Ganga plain is associated with fortifications, NBPW, iron technology, craft specialisation, writing, roads, storage and coinage. Oxford's recent synthesis of early South Asian urbanism likewise treats early coinage as part of the wider transformation of c. 600–300 BCE. The association is strong because towns concentrate strangers, specialised producers, officials and recurring demand, all of which favour standardised exchange. Yet coinage can circulate beyond cities, and urban growth also depends on agrarian surplus, political organisation, transport and labour. A coin does not create a city; a city does not automatically create a coinage. The useful historical question is how monetary instruments helped larger settlements coordinate flows of food, raw materials, taxes, wages and finished goods that could no longer be managed solely through face-to-face reciprocity.

15.23 Rural monetisation was likely uneven and seasonal

The agrarian hinterlands of Mithilā, Vajji and Aṅga supplied cities with grain, oilseeds, animals, fibres, timber, fish and other necessities. Rural producers could encounter money when selling a surplus, paying a tax, hiring labour, visiting a fair, borrowing from a merchant or purchasing salt and manufactured goods. These encounters need not make the entire household budget monetary. Seasonal harvest cycles could produce bursts of market participation followed by months dominated by household production and reciprocal exchange. Archaeology is biased toward durable urban deposits, so the lower visibility of coins in villages must not be interpreted automatically as economic isolation. At the same time, it would be equally unwarranted to project urban coin use uniformly across the countryside. Rural monetisation should be treated as variable by proximity to routes, market frequency, crop surplus, fiscal pressure and social access to exchange.

15.24 Monetary access was socially unequal

Coins are small objects, but their distribution can reflect large inequalities. Wealthy householders, merchants, tax officials and institutions were more likely to handle substantial stores of silver than land-poor cultivators or dependent labourers. Copper and fractional payments could widen access, yet the ability to save money depended on surplus income. Debt could make monetary accounting important even to people

who rarely possessed cash, because obligations might be reckoned in a monetary unit and repaid in produce or labour at agreed valuations. Gender also shaped access through property rights, occupational roles and household control, although individual archaeological coins rarely identify the sex of their users. The social history of monetisation must therefore ask not only whether money existed but who could acquire, save, lend, spend or demand it.

15.25 Religious institutions participated in monetary circuits without becoming ordinary commercial firms

Buddhist and Jain communities developed within the same urban and mercantile environments in which coinage expanded. Texts discuss donations, permissible property, purchases and the handling of valuables, while archaeological religious sites often received gifts from householders, merchants and rulers. Monetary donations could transform private surplus into durable institutional resources and support construction, food, robes, medicines and travel. Yet the economic role of monasteries and renunciant communities followed religious rules and cannot be reduced to profit-seeking commerce. The detailed institutional economy belongs to Chapter 16. Here the point is narrower: the spread of coin and monetised valuation enlarged the range of resources that donors and institutions could mobilise, while religious rules themselves reveal the social presence of money by regulating when and how it could be accepted or used.

15.26 Testing, fraud and counterfeit control reveal the institutional cost of trust

The advantage of metal money is portability; its vulnerability is that metal quality and weight can be manipulated. Ancient monetary administration therefore had to confront clipping, debasement, false metal, unauthorised manufacture and deceptive weighing. Numismatic evidence of variable alloy and textual concern with testing should be read together as signs that trust required work. Officials, money changers, merchants or experienced users could inspect, weigh and test pieces; repeated marks may record stages of such verification in some series. This does not prove a modern central bank or a single empire-wide mint bureaucracy. It demonstrates a more basic institutional principle: a currency becomes useful only when communities possess procedures for distinguishing acceptable from unacceptable payment. The cost of maintaining that confidence is part of the economic history of monetisation.

15.27 Coinage did not require royal portraits, legends or an exclusive state monopoly to carry authority

Later numismatic traditions often announce rulers through portraits and legends, encouraging historians to assume that all coinage should identify a sovereign. Punch-marked money warns against that expectation. Anonymous symbols and standardised weights could command acceptance without naming a king. Some series are plausibly associated with particular polities, and the Magadha–Maurya sequence became exceptionally influential, but issuing authority, validating authority and everyday accepting community are analytically distinct. Merchants can accept old coins after conquest; local authorities can recognise pieces produced elsewhere; and political states can regulate currency that they did not originally manufacture. This flexibility helps explain why monetary circulation can cross political boundaries. It also means that a map of coin finds is not a direct map of sovereignty.

15.28 The expansion of Magadha likely increased monetary integration without erasing regional practices

As Magadha incorporated Aṅga and eventually dominated the middle Ganga plain, larger fiscal, military and administrative networks could favour more widely recognised monetary standards. The extensive Magadha–Maurya punch-marked series is consistent with such integration. But integration should not be imagined as instantaneous replacement of every local form. Older coins remained in circulation, copper issues coexisted with silver, and regional patterns continued. Political consolidation can widen the geographic area in which a coin is accepted while local markets still determine which denominations are convenient. The relationship between empire and currency is therefore reciprocal: states benefit from standardised payments, and widely accepted money can lower the cost of governing distance, but the actual circulation of money depends on merchants, taxpayers, soldiers, producers and institutions repeatedly accepting it.

15.29 Coin counts cannot be converted directly into ancient money supply or per-capita cash use

Archaeological survival is radically selective. Precious metal is hoarded, recovered and remelted; copper corrodes; excavation samples only a fraction of a settlement; old collections may lack find spots; and published reports vary in detail. A site that has yielded many coins may simply have been excavated more extensively than a comparable site. Hoards can inflate regional totals while revealing little about daily turnover. Consequently, it is not possible to calculate a reliable money supply, velocity of circulation or per-capita coin holding for early Mithilā–Vajji–Aṅga from surviving finds. Quantification remains valuable when based on controlled datasets—weights, die or punch groups, stratified counts and hoard composition—but the denominator must be known. This chapter therefore avoids pseudo-statistical claims and uses numbers only where the archaeological or numismatic corpus itself is defined.

15.30 Conclusion: early monetisation was real, consequential and incomplete by design rather than by failure

By the early historic period, the middle and eastern Ganga world possessed durable monetary institutions: silver punch-marked coinage, copper currencies, weight conventions, checking practices, hoarding, textual units of account and state concern with revenue and payment. Vaiśālī and Campā embed coin finds within urban economies, while the Gorho Ghat hoard places substantial punch-marked silver directly in the wider Bhagalpur–Aṅga corridor. These developments made value more portable, divisible and comparable and helped cities, merchants and states coordinate increasingly complex flows. Yet coin did not displace grain, labour, gift, credit or weighed metal. Monetisation spread unevenly across transaction sizes, occupations and settlements. Its significance lies precisely in this mixed system: money enlarged the repertoire of exchange and administration without becoming the sole language of economic life. Chapter 16 examines how Buddhist and Jain institutions operated within this expanding but plural monetary world.

Table 15.1 — Evidence for early money and monetisation, and limits of inference

Evidence	What it supports	What it does not prove alone	Key references / control
Silver punch-marked coin from stratified context	Coin circulation at a dated settlement horizon; association with urban activity	Exact transaction, owner, issuer or proportion of exchange conducted in cash	Stratigraphy + numismatic classification

Evidence	What it supports	What it does not prove alone	Key references / control
Silver coin hoard	Accumulation; coexistence of types; relative chronology; reserve behaviour	Ordinary retail turnover or identity/occupation of depositor	Walsh 1919; hoard analysis
Gorho Ghat hoard: 58 silver punch-marked coins	Substantial punch-marked silver accumulation in the wider Bhagalpur–Aṅga corridor	Uniform monetisation of Aṅga or a specific market network	Walsh 1919; Walsh 1924
Vaiśālī coins within urban assemblage	Monetary objects embedded in a major early historic city	Cash use by every resident or village in the hinterland	Sinha and Roy 1969
Campā cast copper coins	Lower-value monetary instruments within an eastern Ganga urban sequence	Exact denomination, price level or fiscal function of each coin	IAR evidence reviewed in Chapter 14
Weight standard around 32 rattis / c. 3.4 g for many Magadha–Maurya kārṣāpaṇas	Repeatable expectation for silver valuation and classification	Perfect uniformity of every regional or chronological series	Gupta and Hardaker 2014; museum series
Multiple punches / checking marks	Repeated validation, classification and circulation history	A unique named banker, guild or official for every mark	Allan 1936; Walsh 1924; numismatic studies
Textual paṇa / kārṣāpaṇa vocabulary	Money as a socially intelligible unit of value and payment	Exact archaeological coin type or universal contemporary cash use	Olivelle 2013; genre/date control
Arthaśāstra monetary administration	Developed concepts of treasury, minting, testing, wages, fines and revenue	Direct description of every earlier polity or a single fourth-century-BCE bureaucracy	Olivelle 2013
Urbanism + coins + crafts + routes	Conditions favourable to repeated monetised exchange	Coinage as the sole cause of urbanisation	Allchin et al. 1995; Singh 2008

Chapter 16 — Buddhist and Jain institutional economies

Chapter argument. Buddhist and Jain communities in the early eastern Ganga plain should be understood as institutions that reorganised material dependence rather than escaped the economy. Renunciants limited private possession and ordinary production, yet their food, robes, lodging, medicine, travel, buildings and teaching required durable support relationships. Vaiśālī and Campā provide regional anchors through canonical gift narratives, rains residence, monastic archaeology, a relic stupa containing portable valuables, and the Campā Vinaya chapter on hospitality and valid Saṅgha procedure. Jain evidence adds the fourfold community and rigorous lay–renunciant reciprocity. Comparative inscriptions are used to illuminate institutional possibilities, not to fill regional gaps by assumption; later landed and endowed monasteries are kept chronologically separate from the earlier support economy.

16.1 Institutional economy means organised material dependence, not a claim that religion was “really business”

Buddhist and Jain renunciants defined themselves through restraint, non-possession and withdrawal from ordinary household accumulation, yet renunciation did not abolish material needs. Food, clothing, shelter, medicine, water, travel, maintenance and the care of the sick still had to be supplied. An institutional economy begins where those recurring needs are organised through durable relationships between renunciants, lay supporters, settlements and collective rules. The point is therefore not to reduce religion to commerce. It is to ask how a community that rejected ordinary accumulation could persist across seasons and generations. In the middle and eastern Ganga plain, this question is inseparable from urbanisation, merchant activity, political patronage and household surplus. The economic effect of a monastery or mendicant network could be substantial even when its normative ideal opposed private wealth. Conversely, the presence of donors or valuable gifts does not prove that an institution was profit-seeking. This chapter therefore treats economy as the organisation of resources, obligations, labour and exchange around religious communities.

16.2 Five evidence streams must be kept distinct before they are combined

Institutional economies are unusually vulnerable to source confusion. Buddhist Vinaya texts prescribe rules and narrate cases; Jain disciplinary literature describes ideals of mendicancy and lay support; narrative texts preserve memorable donors, journeys and sacred places; archaeology reveals buildings, stupas, tanks, coins and occupation phases; inscriptions, especially from the early centuries BCE and CE outside the immediate region, identify donors and corporate recipients. Each source answers different questions. A rule against accepting money proves that money-handling was normatively regulated; it does not by itself measure how often money circulated through a monastery. A donated grove in a canonical narrative shows a remembered form of institutional patronage; it is not automatically a deed preserved from the event. An excavated monastery proves built institutional presence in the dated phase of that structure; it does not prove that the Buddha or Mahāvīra occupied that precise masonry. The method of this chapter is therefore convergent but controlled: similarities can reinforce a reconstruction only after chronology and genre have been stated.

Institutional economy: reciprocal flows

Renunciation can reject private accumulation while still producing large economic effects.

Figure 60 — Religious institutional economy redistributed resources through reciprocal but non-equivalent flows among donors, renunciants, material provision and social value.

16.3 Renunciation increased dependence on society rather than eliminating economic relations

A householder normally meets material needs through ownership, production, wages, kinship claims or market exchange. A renunciant who gives up productive property and regular occupation transfers much of that burden to a support network. This is a profound economic reorganisation. The monk or nun becomes less tied to a household but more dependent on repeated acts of giving, hospitality and institutional provision. That dependence can create a dense field of reciprocal expectations without becoming a commercial contract. Donors receive teaching, ritual association, prestige, moral satisfaction and the religious value of giving; renunciants receive necessities that permit continued practice. In densely settled areas such as Vaiśālī and Campā, a larger population and more diversified economy could make such support easier to sustain. Yet the same logic also operated in villages, where a small group of mendicants might rely on a narrow circle of households. Institutional stability therefore depended not only on doctrine but on the depth, diversity and seasonality of the surrounding social economy.

16.4 The Buddhist “four requisites” reveal the material minimum of monastic life

Buddhist disciplinary literature repeatedly organises permissible support around basic requisites: robe material, alms food, lodging and medicines or medical necessities. These categories are analytically valuable because they expose the material foundation beneath an ascetic ideal. Robes connect the Saṅgha to textile production, cleaning, dyeing and repair. Food connects it to cultivators, cooks, market provisioning and household surplus. Lodging connects it to land, timber, brick, carpentry, drainage and maintenance. Medicine connects it to plants, oils, ghee, containers and specialist knowledge. The categories are normative rather than a complete inventory of actual consumption, but they show that an enduring monastic community necessarily participated in a wider economy of goods and services. The scale of that participation changed with community size and permanence. A few itinerant monks carrying bowls and robes placed a different demand on local resources from a residential complex with cells, water facilities, paths and recurring repairs. Economic history must therefore distinguish the minimal mendicant package from the later built institution.

Buddhist support: restraint and collective provision

Vinaya rules are normative evidence; actual practice requires archaeology and inscriptions.

Figure 61 — Buddhist support combined individual restrictions on money and property with recurring provision for monastic life and collective continuity.

16.5 Daily alms created a dispersed support system rather than a central tax

Alms collection redistributed small portions of household production toward renunciant communities without requiring a central treasury. A meal given by one household, a handful of grain from another or cloth supplied by a patron could together sustain people who did not cultivate fields or run ordinary businesses. This dispersed mechanism reduced dependence on any single donor while embedding the Saṅgha in everyday settlement life. It also made religious institutions sensitive to harvests, prices, famine, political disorder and the density of sympathetic households. A prosperous city could offer many potential donors, but competition among mendicants and the high cost of urban food could matter as well. The Pāli sources often present giving as voluntary and meritorious, yet repeated dependence makes the relationship institutional even when no fixed assessment exists. From an economic perspective, alms transfer consumable surplus; from a social perspective, they create contact between households and renunciants. The same act therefore belongs simultaneously to subsistence, ethics, reputation and religious affiliation.

16.6 Hospitality to travelling monks shows the infrastructure behind mobility

The Campā Khandhaka of the Mahāvagga begins with a resident monk, Kassapagotta, making extensive arrangements for visiting monks: seats, water for washing feet, assistance with bowls and robes, bathing, gruel and food. The narrative is primarily a disciplinary case, not an economic survey, but its incidental details are revealing. Religious mobility required hospitality infrastructure. A travelling monk did not move through empty space; he depended on residences, local knowledge, water, meals and the labour of hosts. Such provisioning could be supplied by other monks, by lay supporters or by both. The passage also assumes that a residence could “grow” and become attractive to incoming monks, which implies organisational continuity beyond a single charismatic teacher. Campā is therefore important not only because sermons are located there but because the Vinaya remembers it as a place where problems of resident communities, visitors and valid collective procedure required regulation. Institutional geography and material hospitality reinforce one another.

16.7 The rains retreat converted seasonal immobility into recurrent local economic relationships

The annual rains residence reduced long-distance movement during the monsoon and concentrated renunciants for an extended period in particular settlements. This seasonal rhythm had economic

consequences. Food had to be supplied repeatedly rather than once; lodging had to remain usable through wet conditions; robes and medicines required storage and distribution; ties with nearby households became more regular. The Mahāparinibbāna Sutta places the Buddha's final rains near Vaiśālī at Beluva and has monks seek residence in the surrounding area among people with whom they had connections. Whatever the narrative's redactional history, the institutional logic is clear: monsoon residence relied on social networks and available shelter. The rains retreat also encouraged the transition from purely itinerant mendicancy toward recurring residence at known groves and compounds. That did not automatically create large monasteries, but it made durable places economically useful. The religious calendar thus structured demand, mobility and the intensity of lay-monastic contact.

16.8 Ambapālī's grove at Vaiśālī represents a remembered transfer of productive urban land into religious use

In the Mahāparinibbāna Sutta, Ambapālī first provides a meal for the Buddha and the community and then gives her mango grove to the Saṅgha headed by the Buddha. The episode should be read as a canonical memory rather than as a surviving land deed, but it captures a crucial institutional transition: support could take the form not only of consumable food but also of access to a durable place. A grove offered shade, assembly space, lodging potential and a recognised address within the urban landscape. The donor was a woman of high public visibility, which also warns against imagining patronage as exclusively male or royal. Economically, the episode distinguishes a one-time consumable gift from an asset whose usefulness could recur. Socially, it binds a prominent urban patron to a religious community. Historiographically, it is safest to say that early Buddhist tradition considered the donation of parks and groves an appropriate and memorable form of support; the precise legal form of property rights must be reconstructed from broader evidence rather than assumed.

16.9 Competition to host a meal at Vaiśālī shows that giving carried prestige as well as cost

The same narrative describes Licchavis encountering Ambapālī after she had secured the next day's meal invitation and offering a very large sum if she would surrender the opportunity. The stated amount belongs to a literary scene and should not be converted into a reliable market price. Its significance is institutional and social: providing for the Buddha and Saṅgha is represented as a scarce honour for which powerful people competed. Giving therefore had a prestige economy. The donor expended resources but acquired public association with a revered community. Such competition could help religious institutions mobilise surplus without taxation or coercion, while also giving elites a language for generosity. It could, however, reproduce inequality because the most conspicuous gifts were easier for wealthy patrons. Small household alms and spectacular elite donations should therefore be distinguished. Both sustained religious life, but they operated at different scales and generated different forms of visibility.

16.10 Vaiśālī's archaeological remains demonstrate long institutional continuity, not a single frozen "Buddha-period monastery"

The archaeological landscape at Kolhua and ancient Vaiśālī contains stupas, monastic remains, a tank, shrines and an Aśokan pillar. UNESCO's description of the Silk Road component notes remains ranging from the Mauryan period through the post-Gupta centuries, while the Archaeological Survey of India records protected Buddhist remains across the Vaiśālī complex. This long sequence is essential. It confirms that the area became a durable Buddhist institutional landscape, but much of the surviving masonry is later

than the lifetime traditionally assigned to the Buddha. A responsible socio-economic reconstruction therefore separates early textual memory from the dates of excavated structures. The later expansion of brick architecture implies accumulated labour, materials, planning and maintenance, while votive monuments imply recurring patronage. These are strong indicators of an institutional economy in the subsequent centuries. They should not be collapsed into the sixth or fifth century BCE simply because the sacred topography links later buildings to earlier narratives.

16.11 The Vaiśālī relic stupa links ritual memory, valuables and monetisation without proving a monastery treasury

The protected relic stupa at Harpur Basant is especially important for connecting Chapter 15's monetary history with religious institutions. The Archaeological Survey of India describes an early inner stupa and reports a relic casket with ashes mixed with earth; associated finds include a punch-marked coin, beads and gold objects. Bihar Tourism likewise notes the coin among excavated contents. These objects show that valuables and monetary material entered a sacred depositional context. They do not demonstrate that the stupa operated a treasury or that coins financed its construction. Deposited objects can be offerings, commemorative inclusions or items incorporated during a particular building phase. The significance lies in coexistence: early monetisation and religious commemoration occupied the same social world. Sacred institutions could attract valuable objects because people assigned value to memorial presence. The economic and ritual meanings of a coin are therefore not mutually exclusive; context determines which inference is justified.

16.12 Campā's Vinaya chapter makes institutional law part of Aṅga's social history

The ninth Khandhaka of the Mahāvagga is explicitly associated with Campā and is concerned with the validity and invalidity of formal acts of the Saṅgha. Its cases discuss quorum, motions, suspension and collective procedure. These are legal-institutional matters rather than market transactions, yet they have economic significance because durable property, residences and shared resources require rules about who can act for a community and under what conditions. An institution without valid procedure cannot reliably admit members, discipline them, settle disputes or manage common responsibilities. Campā thus appears as part of the remembered geography in which Buddhist corporate procedure was articulated. The text does not prove that every rule originated historically at the stated place, but the association itself is evidence that Campā was imagined as a significant monastic centre. This reinforces the city's role, already established in Chapter 14, as a node of political, commercial and religious movement.

16.13 Buddhist prohibitions on gold, silver and trade separate personal renunciation from the monetary world around the Saṅgha

The Pāli Bhikkhu Vibhaṅga's Nissaggiya Pācittiya rules prohibit a monk from accepting gold and silver, engaging in monetary exchange and engaging in buying and selling. The commentary embedded in the disciplinary tradition treats "silver" broadly enough to include forms used in business. These rules are crucial for economic history because they do not describe a society without money; they regulate how renunciants are to relate to a monetised environment. A prohibition is therefore evidence of a boundary, not evidence of economic isolation. The rule also distinguishes the individual monk's conduct from the needs of a continuing community. Later Vinaya traditions and inscriptions show a range of mechanisms by which lay stewards or corporate arrangements could mediate valuable gifts, but those mechanisms vary by school and

period. For the early Ganga plain, the safest conclusion is that personal money-handling was a recognised disciplinary problem precisely because monetary exchange existed around the Saṅgha.

16.14 Corporate property and individual poverty are not contradictory categories

A recurrent error in the history of monasticism is to assume that if monks renounce possessions, a monastery cannot possess durable assets. Buddhist legal literature eventually makes sophisticated distinctions among personal belongings, communal property, residence property and gifts intended for particular purposes. Gregory Schopen's studies of Indian Vinayas and inscriptions demonstrate that Buddhist communities could function as juridical or corporate bodies with property and financial obligations while still regulating individual possession. Not every one of those developed mechanisms can be projected into early Vaiśālī or Campā. The conceptual distinction, however, is indispensable. A monk may own little while living in a building maintained by a community; a community may accept a donated grove while individuals are barred from treating it as private real estate. This separation allowed renunciation and institutional durability to coexist. It also created the need for rules governing use, inheritance, repair, alienation and the intentions of donors.

16.15 Permanent residences transformed religious communities into consumers of construction and maintenance

Once a religious residence became durable, its economy extended beyond food. Brick-making, timber, roofing, plaster, drainage, wells, paths, doors, mats, lamps and cleaning created recurring demand for labour and materials. Archaeological remains at Vaiśālī illustrate this later built dimension particularly clearly, while Campā's long urban sequence provides the broader craft and supply environment in which religious establishments could operate. Construction need not imply wage labour in every case: work could be donated, commanded, contracted or organised through patrons. Nor should every brick foundation near a sacred site be assumed to be monastic. Where identification is secure, however, the built environment reveals resource concentration. Maintenance is especially important because it is less visible than foundation ceremonies but more continuous. A donated building that cannot be repaired quickly becomes unusable. Institutional economy therefore includes mundane expenditure—water control, replacement materials, cleaning and storage—as much as spectacular patronage.

16.16 Monasteries and mendicant communities created demand without functioning like ordinary households

Religious communities consumed goods, but their consumption pattern differed from that of reproductive households. They did not normally aim to accumulate family property, arrange inheritances for children or expand a domestic estate. Instead, expenditure clustered around sustenance, ritual, teaching, hospitality, buildings and care of members. This difference matters because the same merchant, farmer or artisan could interact with a monastery in a way unlike an ordinary customer. A pot might be donated rather than sold; cloth might be given for merit; a meal might be sponsored publicly; construction might combine hired labour and religious gift. The institution therefore sat across market and non-market exchange. It generated demand that could stimulate production, yet the transaction might be framed as *dāna* rather than purchase. Economic analysis must preserve both dimensions. Reducing all gifts to disguised trade ignores religious motivation; treating all gifts as economically irrelevant ignores their effects on production and redistribution.

16.17 Donor diversity prevents a single “merchant Buddhism” model

Merchants were important patrons of Buddhism in many early historic contexts, and the urban settings of Vaiśālī and Campā make commercial participation plausible. Yet canonical narratives, archaeology and inscriptions across India show a wider donor spectrum: rulers, householders, monks, nuns, artisans, officials and women as well as merchants. Ambapālī’s Vaiśālī episode is a regional reminder that prominent female patrons cannot be erased by a merchant-only narrative. The Licchavis represent political elites; ordinary alms imply much smaller household gifts. Later inscriptions from Buddhist sites elsewhere often name donors with varied occupations and statuses. The institutional economy was therefore resilient partly because it could draw on multiple social groups. This diversity also distributed risk: a community dependent only on a court could suffer when dynasties changed, while one dependent only on local alms could struggle during scarcity. Multiple patronage channels allowed religious institutions to survive political and economic fluctuations more effectively.

16.18 Buddhist nuns must be included as economic actors, not treated as an invisible appendage

The history of Buddhist institutions has often been written from male monastic rules and male donor lists. Gregory Schopen has emphasised inscriptional evidence showing Buddhist nuns acting as donors and legal persons in early India. The precise scale and chronology vary by region, and such evidence should not be mechanically transferred to Vaiśālī. Yet Vaiśālī is central to Buddhist traditions about the establishment and presence of the bhikkhunī community, making female institutional history especially relevant. Nuns required food, robes, lodging and medicine, organised teaching and discipline, and interacted with laywomen and laymen. Their material support could therefore generate its own networks. The archaeological identification of specific nunneries is often uncertain, and later architectural interpretations at Kolhua must be dated carefully. The larger conclusion is secure: a socio-economic history that counts only monks and male donors underestimates both the consuming population and the channels through which wealth, merit and authority circulated.

16.19 Merit functioned as a moral account of giving without becoming a literal currency

Dāna linked material transfer to religious consequence. Donors did not simply lose food, cloth or land; they understood giving as ethically productive. This can be described as a “merit economy” only if the metaphor is controlled. Merit was not a coin with a uniform market price, and canonical statements about the fruit of giving are not exchange-rate tables. Nevertheless, belief in religious benefit helps explain why people repeatedly transferred resources to communities that did not return equivalent commodities. The institution converted material support into teaching, ritual association, memorialisation and a moral narrative of generosity. Public monuments and donor inscriptions in later centuries made that association durable by naming givers and intended beneficiaries. In early Vaiśālī, the narrative prestige surrounding Ambapālī and the Licchavis performs a similar literary function. Merit therefore reduced neither to altruism nor to profit; it was a culturally specific way of assigning value to transfers beyond immediate material reciprocity.

16.20 Patronage could reproduce inequality even while redistributing resources

Religious giving moves resources, but redistribution is not automatically egalitarian. A wealthy patron could finance a grove, building or large meal and receive public visibility unavailable to a poor donor. A ruler

could attach political legitimacy to support for a revered community. Merchant donors could strengthen networks of trust and reputation. At the same time, smaller gifts allowed ordinary households to participate in institutional life, and food redistribution supported people outside household production. The result was a layered economy of generosity. Religious institutions could soften some inequalities by feeding residents and travellers while also giving elites new arenas for status. Economic history must therefore avoid two opposite myths: monasteries were neither merely extractive accumulators nor automatically charitable levellers. Their effects depended on the form of the gift, the control of property, the social identity of recipients and the wider distribution of land and income.

16.21 Jain institutional economy begins with the fourfold Saṅgha, not with the monastery alone

Jain tradition conceptualises the community as fourfold: monks, nuns, laymen and laywomen. This is economically significant because the institution is not identical with a residential monastery. Mendicants pursue rigorous non-possession and itinerancy, while householders remain economically active and support renunciants. The fourfold model therefore embeds asceticism inside a broader social body. The laity supplies food, shelter and other permissible necessities; renunciants provide teaching, discipline and a living model of the path. Jain sources preserve highly idealised numbers for Mahāvīra's followers, so those totals should not be treated as demographic statistics. The structural principle is more reliable than the numbers: religious continuity required both renunciant specialists and a lay support base. This arrangement could operate across towns and villages without the same architectural concentration as a large Buddhist monastery. Institutional economy must therefore include networks and recurring relationships, not only buildings and treasuries.

Jain fourfold community and material support

Comparative merchant patronage does not make every early Jain supporter a merchant.

Figure 62 — The Jain fourfold Saṅgha linked monks and nuns practising strict renunciation with laymen and laywomen who remained within household economic life.

16.22 Jain aparigraha and alms discipline created strong limits on direct accumulation

Non-possession is central to Jain mendicant ethics. Monks and nuns are expected to restrict possessions, food acquisition and attachment with a severity that makes ordinary economic self-provision difficult. Disciplinary literature devotes close attention to alms, acceptable food, movement, seasonal residence and the avoidance of harm in everyday acts. These rules are religious disciplines, but they also shape economic interaction. A mendicant dependent on prepared food cannot simply substitute unrestricted purchasing for alms without undermining the renunciant ideal. The burden of production therefore remains with householders. This creates a deliberate asymmetry: the ascetic offers no equivalent commodity in return,

while the lay supporter gains religious instruction and the merit of supporting disciplined renunciation. The economic relationship is thus reciprocal without being a market exchange. Because Jain rules differ across sectarian and chronological traditions, later Śvetāmbara or Digambara practice should not be projected wholesale into the earliest period.

16.23 The Jain lay community connected religious life to agriculture, crafts and commerce

Lay Jains were not required to abandon productive work. Their less absolute vows were designed for household life, allowing participation in property, trade and family obligations under ethical constraints. This made the lay community the principal material interface between mendicants and the economy. S. B. Deo's survey of inscriptions concludes that, across many later sites, trading groups formed an important source of lay support, while other inscriptions also record artisans, officials and women. That comparative pattern helps explain why Jainism could flourish in urban and commercial settings, but it should not be turned into an ethnic or occupational stereotype for early Vaiśālī. The key institutional point is broader: householders could translate market earnings or agrarian surplus into alms, lodging, images, memorials and other religious gifts. Jain renunciation therefore depended on a lay economy it did not itself reproduce through ordinary household labour.

16.24 Jain women occupied both renunciant and donor roles within the institutional economy

The fourfold Saṅgha explicitly includes nuns and laywomen. Jain tradition often remembers very large communities of nuns, although literary totals are not census data. More concrete evidence from early historic Mathurā includes numerous female donors in Jain dedicatory inscriptions, sometimes identified through kinship and sometimes associated with monks or nuns who prompted the donation. Mathurā lies outside Mithilā, Vajji and Aṅga, so it serves here as a comparative control rather than direct regional proof. It demonstrates, however, that women could command or direct resources within early Jain patronage networks. For the regional history, this prevents the support economy from being reconstructed solely through male merchants and male ascetics. Laywomen could mediate household wealth toward religious ends, while nuns constituted a large category of dependent and authoritative renunciants. Gender therefore shaped both access to resources and the institutional channels through which giving acquired religious meaning.

16.25 Mahāvīra's Vaiśālī associations make Vajji central to Jain memory, but biography and archaeology must not be collapsed

Jain traditions associate Mahāvīra with the Vaiśālī–Videha region, including Kundagrāma and Licchavi-linked social networks. These traditions make the area fundamental to Jain sacred history and help explain the enduring Jain significance of modern Vaiśālī. Yet the archaeological problem is difficult. A later temple or pilgrimage site cannot by itself authenticate a precise sixth- or fifth-century BCE biographical location. Nor should traditional dates be treated as archaeometric measurements. The strongest historical conclusion is regional: Jainism's formative memory is deeply embedded in the same eastern Ganga political landscape that generated Vajji and Videha traditions. That memory implies an early support environment of settlements, households and itinerant routes capable of sustaining mendicants. The economic history should therefore reconstruct networks of mobility and lay support while keeping individual biographical claims at the level warranted by their textual transmission.

16.26 Campā belongs to Jain sacred geography as well as Buddhist institutional geography

Jain tradition associates Campā with the Tīrthaṅkara Vāsupūjya and with later Jain pilgrimage, adding a second religious memory to the city already prominent in Buddhist texts. This layered sacred geography is historically important because it shows how the same urban centre could be claimed and revisited by different renunciant traditions. The early date and exact material form of particular Jain establishments at Campā are harder to establish than the Buddhist Vinaya association, so the evidence must remain asymmetrical. The socio-economic implication is nevertheless significant: a prosperous river city could support multiple communities through households, markets, donors and hospitality. Shared urban resources did not require institutional identity. Buddhist monks and Jain mendicants could depend on the same grain-producing hinterland, textile workers and transport routes while maintaining sharply different rules of discipline. Religious pluralism was therefore also a pluralism of support networks operating within a common economic landscape.

16.27 Mathurā's early Jain inscriptions provide comparison for donor organisation, not a template for Vajji and Aṅga

Kankali Tila and other Mathurā material from the early centuries BCE and CE preserve an exceptionally rich Jain donor record. Inscriptions identify lay donors, women, occupational groups, monks, nuns and organised lineages, while votive tablets and images show resources being converted into durable religious objects. This evidence is indispensable for understanding what a mature early historic Jain institutional economy could look like. It is not evidence that the same donor composition or monument form existed at Vaiśālī at the same date. Regional economies, sectarian histories and archaeological survival differ. Comparison is useful when it establishes possibilities—female patronage, merchant support, named monastic lineages, durable gifts—without replacing missing local evidence. The chapter therefore uses Mathurā as a control case: it demonstrates the institutional capacity of Jain communities in early historic India while leaving the exact scale of early Vajji and Aṅga patronage open.

16.28 Buddhist and Jain communities could compete for patronage without forming a zero-sum religious market

Cities and route corridors often hosted multiple renunciant groups. Competition for meals, lodging, teaching audiences and elite patronage was possible, and polemical texts attest intellectual rivalry. Yet a household could support more than one type of ascetic, and rulers could patronise several traditions across a reign. Religious affiliation was therefore not necessarily an exclusive consumer choice. Different communities offered different disciplinary ideals, ritual relationships and teaching networks, while drawing from overlapping pools of surplus. Competition may have encouraged institutional differentiation and public generosity, but coexistence was equally important. In Vaiśālī and Campā, the presence of multiple traditions should be treated as part of urban social complexity rather than as evidence for a simple winner-and-loser sequence. The wider economy was large enough to contain households, Brahmanical specialists, Buddhist monks, Jain mendicants and other ascetics simultaneously.

16.29 Later land grants, endowed funds and great monasteries reveal a trajectory that must not be retrojected

By the early centuries CE and especially the Gupta and post-Gupta periods, inscriptions from various parts of India document monasteries receiving land, permanent endowments and substantial monetary gifts.

Schopen's work shows that some Buddhist legal traditions developed sophisticated rules for corporate wealth, loans and property; later eastern institutions such as Nālandā became major landed and endowed establishments. Jain communities likewise accumulated temples, endowments and complex patronage networks in later centuries. These developments matter because they reveal what religious institutions could become. They do not prove that the Saṅgha at Vaiśālī in the Buddha narratives already possessed comparable estates or financial portfolios. Historical sequence must be preserved. Early alms, grove gifts, residences and collective procedures created institutional capacities; later political economies expanded some of those capacities dramatically. The direction of development is therefore from documented early support relationships toward more complex property regimes, not backward from medieval wealth to an imagined wealthy monastery in every early city.

Evidence map: regional anchors and comparative controls

Sacred memory, textual rules, archaeology and inscriptions must be dated independently.

Figure 63 — Regional evidence from Vaiśālī and Campā must be distinguished from comparative early Indian evidence and from later endowed monastic systems.

16.30 Conclusion: religious renunciation generated institutions by reorganising rather than escaping material life

Buddhist and Jain communities in the eastern Ganga world were economically consequential because they organised dependence. Renunciants withdrew from ordinary accumulation, but their food, robes, shelter, medicine, travel and teaching required recurrent transfers from households and patrons. Vaiśālī provides unusually rich regional evidence: canonical memories of meals and a grove donation, rains residence, a later monumental Buddhist landscape and a relic stupa containing valuable objects. Campā contributes the Vinaya's detailed concern with hospitality and valid Saṅgha procedure inside an important Āṅga city. Jain tradition adds the fourfold Saṅgha, rigorous non-possession, lay support and deep Vaiśālī associations, while early Mathurā inscriptions provide a comparative view of donor diversity. The combined evidence supports neither a romantic picture of institutions outside the economy nor a reductive picture of monasteries as businesses. Religious institutions were distinctive organisations that converted surplus into subsistence, durable places, teaching, memory and merit. Their growth linked urbanisation, household economies, gender, mobility and patronage, preparing the institutional landscape examined in the next chapter on education, debate and intellectual communities.

Table 16.1 — Evidence for Buddhist and Jain institutional economies, and limits of inference

Evidence	What it supports	What it does not prove alone	Key references / control
DN 16: Ambapālī	A canonical model of elite	Exact legal deed, date of an	Walshe 1995; genre

Evidence	What it supports	What it does not prove alone	Key references / control
meal and mango-grove gift at Vaiśālī	female patronage; distinction between consumable gift and durable place	excavated building, or market value of the grove	control
DN 16: rains residence at Beluva near Vaiśālī	Seasonal residence and dependence on local social networks	A permanent brick monastery in the Buddha's lifetime	Walshe 1995; archaeological dating
Kolhua / Vaiśālī monastic and stupa remains	Long-lived Buddhist institutional landscape with repeated construction and patronage	That all surviving masonry belongs to the sixth–fifth century BCE	Sinha and Roy 1969; ASI/UNESCO archaeological control
Vaiśālī relic stupa with punch-marked coin and valuables	Intersection of sacred deposition, portable value and early monetisation	A monastery treasury, routine cash budget or precise donor identity	ASI context + numismatic caution
Mahāvagga IX, Campā Khandhaka	Remembered institutional geography; hospitality; formal Saṅgha procedure and corporate governance	That every rule originated historically at Campā or measures local wealth	Horner 1938–1966; Vinaya genre control
Nissaggiya Pācittiya rules on money and trade	Normative boundary against personal money acceptance, monetary transactions and buying/selling	Absence of money around monks or absence of collective property	Vinaya rules + Wijayaratna 1990
Jain fourfold Saṅgha and mendicant discipline	Structural dependence of monks/nuns on laymen/laywomen; organised lay–renunciant reciprocity	Traditional follower totals as census data or a uniform economic occupation for all laity	Jaini 1979; Dundas 2002; Deo 1956
Early Jain donor inscriptions at Mathurā	Comparative proof of female, mercantile, artisan and monastic participation in durable religious giving	The same donor mix or institutional scale in early Vaiśālī or Campā	Lüders 1961; Quintanilla 2007
Later Buddhist/Jain endowments and large monasteries	Long-term trajectory toward landed, endowed and financially complex religious institutions	Equivalent estates or financial mechanisms in fifth-century BCE Vajji/Aṅga	Schopen 2004; strict chronological control
Religious donations generally	Transfer of surplus into subsistence, buildings, memorials and institutional continuity	That donors acted only for profit, only for merit, or that redistribution was egalitarian	Multi-source social analysis

Chapter 17 — Education, debate and intellectual communities

Chapter argument. Education in early Videha, Vajji and Aṅga was not a single “school system” and should not be reconstructed by projecting later universities or medieval scholastic institutions into the first millennium BCE. Knowledge moved through households, teacher–pupil lineages, courts, ritual specialists, renunciant communities, urban audiences and mobile networks. Late Vedic and Upaniṣadic traditions place Videha prominently within a culture of learned patronage and disputation; Buddhist sources make Vaiśālī and Campā part of a wider world of travelling teachers, collective recitation, doctrinal argument and institutional discipline; Jain traditions add another durable network of teachers, mendicants and lay supporters. These sources do not give literacy rates, school enrolments or a census of occupations. Read together and with archaeological control, however, they reveal a plural social infrastructure of learning in which memory, speech, reputation, mobility and patronage were as important as buildings.

17.1 Education is a social relationship before it is a building

For the early historic eastern Ganga plain, “education” must be defined broadly enough to include the organised transmission of texts, ritual competence, ethical discipline, argument, craft knowledge and institutional memory. The surviving evidence rarely identifies a structure whose exclusive function was schooling. A teacher’s household, a royal audience, a grove used by wanderers, a monastic residence, an assembly hall or a ritual setting could all become places of instruction. This does not mean that learning was informal in the sense of being casual. Vedic recitation required exact training; renunciant orders regulated admission, seniority and discipline; philosophical dialogues presupposed recognised standards of competence. The institutional form was often personal and networked rather than architectural.

17.2 Five evidence streams must be separated before they are combined

The history of learning is unusually vulnerable to retrospective idealisation. Late Vedic and Upaniṣadic texts preserve teacher lineages, ritual instruction and famous debates, but their literary form is not a stenographic record of particular court sessions. Buddhist Nikāya and Vinaya materials preserve teaching encounters, recitation and institutional disputes, but they were transmitted and arranged within Buddhist communities. Jain canonical traditions likewise preserve mendicant and lay pedagogies through later redactional histories. Archaeology can locate settlements, monasteries, routes and inscriptions yet normally cannot identify the content of a lesson. Later scholastic institutions provide trajectories, not templates for the earlier period. Historical reconstruction becomes strongest where several streams converge without being collapsed into one another.

Figure 64 — Early intellectual history requires separate control of textual, institutional and material evidence before synthesis.

17.3 Oral transmission was a technology of precision, not a primitive absence of writing

Vedic learning depended heavily on trained memory, controlled pronunciation and repeated recitation. Oral transmission could preserve complex verbal material with techniques specifically designed to detect error. The teacher therefore carried not merely “information” but an embodied repertoire of sound, sequence and correction. This helps explain why the history of early education cannot be measured by the number of surviving manuscripts. Writing eventually became important across administration, commerce and religious cultures, but oral authority remained powerful even after scripts were in use. The coexistence of orality and literacy is historically more accurate than a simple progression from an “oral age” to a “written age.”

17.4 The teacher–pupil household linked learning to kinship, service and discipline

Brahmanical educational traditions describe students residing with or attaching themselves closely to a teacher. Such arrangements made learning a social relation sustained by food, service, discipline and long-term trust. The household or ācārya-centred tutorial was therefore both pedagogical and economic: someone had to feed the learner, release time from productive labour, and support the teacher. Access depended on status, family resources, recognised eligibility and the willingness of a teacher to accept a pupil. The resulting system could transmit knowledge very intensively while remaining socially selective. It should not be romanticised as universal village schooling.

17.5 Access to formal learning was unequal even when knowledge circulated widely

The presence of celebrated learners from different social locations does not prove equal access. Vedic study was closely associated with varṇa and initiation rules in Brahmanical normative texts; wealth and household position affected who could devote years to study; gender expectations limited many forms of formal training. At the same time, the broader intellectual landscape was more porous than a single

normative scheme suggests. Renunciant communities recruited outside hereditary priestly lineages, urban audiences heard public teachings, and practical skills moved through households and occupations. Early society therefore combined restricted specialist education with wider circulation of stories, ethical teaching, ritual knowledge, techniques and public argument.

17.6 Videha's intellectual importance is first visible as a literary geography of patronage

The Bṛhadāraṇyaka Upaniṣad repeatedly associates Janaka of Videha with learned inquiry and with Yājñavalkya. This makes Videha one of the most prominent eastern settings in late Vedic philosophical literature. The safest historical inference is not that Mithilā possessed a “university” or a permanent academy with departments, but that the literary tradition regarded the Videha court as a place where patronage, prestige and difficult questioning could meet. Such a representation itself is socially important: it locates intellectual authority partly in a royal arena and shows that reputation could draw teachers and interlocutors across regional networks.

17.7 The Janaka–Yājñavalkya dialogues show patronage and inquiry operating together

In the Bṛhadāraṇyaka, exchanges between Janaka and Yājñavalkya combine questioning with gifts and recognised status. Cattle and other rewards belong to the narrative economy of learned distinction. They should not be treated as a salary scale or evidence for a bureaucratic educational office. They do show that knowledge could generate material patronage and public prestige. The ruler is not merely a passive sponsor: Janaka is represented as asking subtle questions and evaluating answers. This literary model matters for social history because it depicts intellectual life as reciprocal—teachers gain patronage and reputation, while rulers gain association with authoritative knowledge.

17.8 Gargī's participation demonstrates a remembered female intellectual presence without proving general equality

The famous questioning of Yājñavalkya by Gargī Vācakanvī in the Bṛhadāraṇyaka places a learned woman inside a high-status philosophical contest. The passage is strong evidence that the textual tradition could imagine, value and preserve female philosophical agency at the highest level. It is not evidence that women as a class enjoyed the same educational access as men. The proper historical use of Gargī is therefore double: her visibility prevents an all-male reconstruction of intellectual life, while the exceptional character of the episode warns against converting one named figure into a statistic about general female literacy or schooling.

17.9 Maitreyī shows that philosophical instruction could be represented within the household

The Maitreyī–Yājñavalkya dialogue locates profound inquiry within a domestic relationship rather than a public assembly. Its subject is philosophical, but its social setting is equally instructive: property, renunciation, marriage and teaching intersect in a single conversation. Maitreyī is represented not simply as receiving doctrine but as questioning the value of wealth in relation to immortality. The episode broadens the geography of learning from court and grove to household. It also cautions against equating “education” only with institutions visible to archaeology.

17.10 Learned contests could convert intellectual competence into reputation and resources

Debate in early Indian literature is often competitive. A successful teacher gains disciples, honour and patronage; an unsuccessful claimant risks loss of standing. The cattle offered in the Janaka cycle dramatise this connection between knowledge and reward. In Buddhist texts too, reputations precede travelling teachers and attract audiences. The social economy of debate therefore included non-material and material returns: prestige, followers, hospitality, gifts and access to rulers or wealthy householders. These incentives did not make philosophy reducible to economic calculation, but they helped sustain specialists whose time was not devoted entirely to subsistence.

17.11 Intellectual communities were mobile networks rather than territorially sealed schools

Teachers, students, monks, nuns, Brahmans and wanderers moved between courts, towns, villages, groves and monastic residences. Routes that carried merchants and officials also carried arguments, stories, ritual techniques and reputations. The eastern Ganga plain's urban growth increased the density of audiences and patrons without erasing rural or itinerant forms of learning. Videha, Vaiśālī, Campā and Magadha should therefore be treated as nodes in overlapping circuits. A famous teacher could be associated with one court or city while teaching across a much wider landscape.

Figure 65 — The Videha debate traditions model intellectual life as an interaction among patronage, established teachers, questioning and reputation.

17.12 Language plurality was an intellectual resource as well as a social boundary

Different knowledge communities operated with different linguistic repertoires. Vedic learning privileged carefully preserved Vedic language and recitational forms. Early Buddhist and Jain traditions remembered teaching in speech accessible beyond Vedic ritual specialists, although the surviving Pāli and Jain Prakrit canons are products of long textual histories rather than tape recordings of the sixth or fifth centuries BCE. Everyday populations spoke changing Middle Indo-Aryan varieties that cannot be mapped neatly onto

modern language boundaries. Linguistic plurality widened audiences in some settings while specialist registers preserved authority in others.

17.13 The history of writing must not be used to erase the history of memory

The Aśokan inscriptions of the third century BCE provide the first large, securely datable corpus of deciphered writing across much of the subcontinent, demonstrating that scripts were by then effective instruments of public communication. Earlier use of writing remains debated and unevenly evidenced. Neither conclusion changes the central role of oral transmission in Vedic and renunciant communities. Even after writing was available, memorisation, recitation and live exposition remained powerful because authority was carried by recognised persons and lineages. Literacy and orality were complementary technologies, not mutually exclusive stages.

17.14 Early literacy was socially consequential without being measurable as a population rate

Inscriptions, seals, marks and administrative practices show growing uses of graphic communication in the early historic period, especially by the Mauryan age and after. Yet surviving evidence cannot yield a credible literacy percentage for Vaiśālī, Campā or Mithilā. Reading and writing may have been concentrated among scribes, officials, merchants, religious specialists and others whose occupations created demand. A society can use writing extensively in administration while large parts of its knowledge remain oral. Claims of universal literacy or universal illiteracy are therefore equally unwarranted.

17.15 Debate was a public technology for comparing teachers and claims

Early Buddhist literature repeatedly depicts conversations among rival teachers, householders and wanderers. Such scenes show an intellectual market in the sociological sense: multiple claimants to authority addressed overlapping audiences and were compared by listeners. The Kutūhalasālā or “debating hall” tradition is especially suggestive because it imagines ascetics, Brahmins and wanderers of different affiliations sitting together and discussing contested doctrines. Whether every such hall was a permanent municipal building cannot be established. The stronger inference is that inter-sectarian discussion was recognisable enough to become a named social setting.

17.16 Campā preserves unusually concrete evidence for a Brahman teacher and student circle

The Soṇadaṇḍa Sutta places the Buddha at Campā beside Gaggara’s lotus pond and presents the Brahman Soṇadaṇḍa as a major local figure. In the textual account he is described as a teacher of mantra knowledge with hundreds of young students. The number should not be read as an enrolment register, but the description is important: Campā is represented not only as a commercial and political centre but also as a place where Brahmanical learning had organised teachers, pupils and status. This gives Aṅga a specific intellectual anchor rather than leaving education as a generic feature of “ancient India.”

17.17 The Soṇadaṇḍa encounter shows learned communities sharing an urban audience

The importance of the Campā episode lies not only in its doctrinal content. Brahmins and householders hear of the Buddha’s arrival; Soṇadaṇḍa weighs the reputational consequences of visiting him; a large audience becomes part of the encounter. The narrative therefore links intellectual authority to urban

communication. News moves, reputations matter, followers compare teachers, and local elites participate. Buddhist and Brahmanical learning appear as overlapping public worlds rather than isolated systems. This does not prove constant harmonious exchange: competition, hierarchy and polemic were part of the same environment.

17.18 The samaṇa-brāhmaṇa landscape multiplied possible careers of knowledge

The eastern Ganga plain hosted ritual specialists, hereditary teachers, household philosophers, Buddhist monks and nuns, Jain mendicants, Ājīvikas and other wanderers remembered in Buddhist and Jain sources. Their doctrines differed radically, but sociologically they shared certain practices: travelling, teaching, attracting disciples, accepting forms of support and disputing rivals. This plurality offered audiences alternatives to lineage-based ritual authority while creating new forms of discipline and hierarchy. Intellectual history must therefore be written as a history of communities, not only as a sequence of abstract philosophical propositions.

17.19 A debating hall is evidence for organised discussion, not automatically for a school building

The term *kutūhalasālā* in Buddhist literature is often translated as a debating hall or hall for public discussion. It signals a recognised social arena where persons of different views could gather. Archaeology, however, cannot normally match a particular excavated hall to a named canonical debate. The category is most useful as evidence for institutionalised discussion: audiences expected teachers to answer questions in front of others, reputations could be tested publicly, and intellectual pluralism had spaces—whether permanent or temporary—in which it became socially visible.

17.20 Buddhist pedagogy used dialogue, repetition, lists and graduated explanation

The early Buddhist discourses are structured for oral teaching. Repeated formulas stabilise memory; numbered lists organise complex doctrine; similes translate abstractions into familiar experience; questions allow a teacher to diagnose an interlocutor's assumptions. This literary organisation reflects pedagogical priorities even when the canonical wording reached its surviving form over time. Instruction was not confined to formal sermons. Monks taught one another, senior members corrected juniors, lay followers asked questions, and travelling teachers adapted explanation to different audiences. Learning was therefore both doctrinal and practical.

17.21 The Saṅgha created a durable learning community through discipline and seniority

Chapter 16 examined the material economy of the Saṅgha; intellectually, the same institution preserved rules, narratives, recitation practices and interpretive authority. Ordination inserted a person into a hierarchy of seniority and obligation. Training required learning conduct as well as doctrine. A monastery or residence could therefore become a place of sustained education without resembling a modern college. The decisive institutional feature was continuity: teachers could die or travel while communal rules, recitation and succession maintained a framework in which new members were trained.

Figure 66 — *Campā’s textual landscape brings Brahman students, an itinerant Buddhist Saṅgha, household audiences and other wandering teachers into one urban field.*

17.22 Collective recitation was both pedagogy and institutional quality control

In oral communities, remembering together can serve as a method of verification. Buddhist traditions about councils emphasise recitation and agreement over doctrine and discipline; Vedic traditions developed their own highly technical recitational safeguards. These are not identical institutions, but they show a shared historical problem: how to preserve authoritative speech when the primary medium is human memory. Correction is social. A learner’s performance is tested against teachers and peers, and communal repetition identifies divergence. The history of education therefore includes practices of quality control long before written examinations became central.

17.23 Vaiśālī’s Second Council tradition reveals deliberation across a regional monastic network

The Vinaya traditions locate a major disciplinary controversy at Vaiśālī roughly a century after the Buddha’s death, centred on disputed practices remembered as the “ten points.” Accounts differ in details and later sectarian narratives should not be harmonised into a single modern transcript. Nevertheless, the convergence of multiple Vinaya traditions makes Vaiśālī an important site in the history of institutional deliberation. Senior monks are imagined travelling, consulting, comparing precedent and reaching decisions. This is intellectual history in a practical register: interpretation of rules, authority of memory and procedure within a translocal community.

17.24 Jain intellectual transmission depended on the fourfold community

Jainism’s fourfold Saṅgha—monks, nuns, laymen and laywomen—created several channels through which doctrine and discipline could circulate. Mendicants required intensive training in conduct, memorised teaching and exposition; lay followers learned vows, narratives and ethical categories while remaining embedded in household economies. Jain canonical traditions were preserved through long processes of recitation, collection and redaction, and different sectarian accounts of those processes must be

distinguished. For the Vaiśālī–Videha region, the safest conclusion is that Jain memory places it within an early, mobile teaching network rather than proving a fixed academy at a particular excavated location.

17.25 Women were teachers, interlocutors, nuns and lay transmitters, but evidence remains uneven

Gargī and Maitreyī prevent late Vedic intellectual history from being written as exclusively male. Buddhist nuns and the verses attributed to early bhikkhunīs preserve another form of female learned identity, while Jain tradition gives nuns a constitutive place in the fourfold community. Laywomen also supported religious teachers and transmitted household practice. Yet the documentary record is asymmetrical, and male institutions generated much of the surviving literature. Named women therefore show real possibilities and roles without justifying a claim that gender ceased to structure access, authority or mobility.

17.26 Practical knowledge moved through apprenticeship even when texts remain silent

A social history of education cannot stop with philosophers and renunciants. Potters, metalworkers, builders, weavers, boatmen, cultivators, traders, accountants and healers all depended on learned techniques. Much of this knowledge was embodied and transmitted through observation, repeated practice and correction within households or occupational groups. Archaeology reveals products and technological sequences more readily than lesson plans. The absence of written manuals for a craft in a particular period therefore does not imply absence of systematic training. Skill transmission was one of the largest educational processes in everyday society.

17.27 Patronage connected intellectual communities to households, markets and political power

Teachers and renunciants required time, food, lodging and social protection. Courts could supply conspicuous gifts; merchants and householders could provide daily support; monastic endowments became more important in later periods. Patronage influenced where teachers could remain, how large a community could become and which reputations travelled. It did not mechanically determine doctrine. Intellectual communities retained internal rules and could criticise patrons. The important point is structural: sustained learning depended on surplus resources generated elsewhere in society, making education part of economic and political history rather than a separate realm.

17.28 Roads, ferries and cities were infrastructure for ideas as well as commodities

Earlier chapters traced riverine and overland movement through Mithilā, Vaiśālī, Campā and the Magadhan corridor. The same routes lowered the cost of intellectual mobility. A teacher's reputation could move with disciples and travellers; a renunciant could follow seasonal circuits; students could seek recognised specialists; patrons could host visiting communities. Urban centres intensified encounters because they concentrated audiences, wealth and lodging, while rural settlements remained essential sources of food and recruits. Intellectual geography was therefore produced by mobility, not simply by the location of famous monuments.

17.29 Later “university” models must not be projected onto early Videha, Vaiśālī or Campā

Nālandā’s great monastic educational complex belongs chiefly to the first millennium CE, many centuries after the early historic settings discussed here; Vikramaśīlā is later still. Taxila was an important ancient centre of teachers and students, but even there scholars caution against treating it as a modern centralised university. For early Videha, Vaiśālī and Campā the evidence supports courts, teacher households, urban debate, travelling renunciants and monastic training—not a campus with a central administration, faculties and enrolment registers. Avoiding the word “university” in this context is not a downgrading of intellectual achievement; it is chronological precision.

17.30 Conclusion: the eastern Ganga plain sustained plural intellectual communities through speech, mobility and institutions

Education in early Mithilā–Videha, Vajji and Aṅga was distributed across several social forms. The Videha debate traditions connect rulers, learned specialists, women interlocutors, gifts and reputation. Campā’s Buddhist narrative world shows Brahman teachers and students sharing an urban field with itinerant renunciants and household audiences. Vaiśālī’s council tradition demonstrates the capacity of a translocal monastic community to gather, argue about rules and preserve institutional memory. Jain communities add another durable teacher–mendicant–lay network. Beneath these named traditions lay the much larger transmission of practical knowledge through households and occupations. The resulting intellectual landscape was neither a single Brahmanical school system nor a chain of ancient universities. It was a networked society of learning in which memory, disciplined speech, mobility, patronage and public argument created enduring communities of knowledge.

Figure 67 — Knowledge circulated among Videha/Mithilā, Vaiśālī/Vajji, Campā/Aṅga and the Magadhan corridor through mobile people and institutions rather than a centralized university system.

Table 17.1 — Evidence for education, debate and intellectual communities, and limits of inference

Evidence	What it supports	What it does not prove alone	Key references / control
Bṛhadāraṇyaka Upaniṣad: Janaka–Yājñavalkya cycles	Videha as a prestigious literary setting for patronage, questioning and learned reputation	A permanent “university,” a transcript of one historical court, or population-wide education	Olivelle; Brereton & Jamison; Scharfe
Gargī and Maitreyī dialogues	Remembered female philosophical agency in courtly and household settings	Gender equality in educational access or female literacy rates	Olivelle; Brereton & Jamison
Vedic recitational traditions	Highly disciplined oral transmission and teacher-dependent training	Absence of writing or universal access to Vedic study	Scharfe; Witzel; Staal
Aśoka and other early inscriptions	Secure large-scale use of writing by the third century BCE and expanding epigraphic communication	A literacy percentage for Vaiśālī, Campā or Mithilā	Salomon; Falk
Soṇadaṇḍa Sutta (Campā)	A textual image of a major Brahman teacher, mantra students and an urban audience in Aṅga	A literal enrolment census or archaeological identification of a school	Walshe; Rhys Davids
Kutūhalasālā traditions	Recognised spaces of inter-sectarian discussion among ascetics, Brahmins and wanderers	That every debating hall was a purpose-built academy	Bodhi; Buddhist Nikāya tradition
Buddhist Vinaya and monastic practice	Training, seniority, recitation, correction and institutional continuity	That early monasteries were modern colleges or economically self-sufficient universities	Horner; Schopen; Wijayaratna
Second Council traditions at Vaiśālī	Translocal deliberation over discipline and authority of remembered rules	A single uncontested chronology of sectarian schism	Prebish; Dutt; Vinaya traditions
Jain canonical and monastic traditions	Teacher–mendicant–lay transmission through the fourfold community	A fixed early academy at Vaiśālī or complete reconstruction of earliest canon formation	Dundas; Jaini; Deo
Craft archaeology and technological sequences	Long-term transmission of practical skills through apprenticeship and repeated practice	The names, curricula or social organisation of individual workshops without additional evidence	Singh; Sharma; archaeological reports

Chapter 18 — Health, medicine and the body

Chapter argument. Health in early Mithilā–Videha, Vajji and Aṅga must be reconstructed from bodily vulnerability, care relationships, urban infrastructure, monastic regulation, specialist healing and the environmental conditions of dense settlement. The chapter does not project classical Āyurveda backward as a fully formed regional system, diagnose ancient populations from modern disease maps, or turn wells and drains into evidence for hospitals. Instead it separates archaeological, Buddhist, Jain, Mauryan inscriptional and later medical-textual evidence, then asks where they genuinely converge.

18.1 Health history begins with bodies under constraint, not with a timeless medical system

A social history of health in early Mithilā–Videha, Vajji and Aṅga must begin from ordinary bodily vulnerability: hunger, fever, digestive illness, wounds, childbirth, ageing, exhaustion, infection and the environmental burdens of dense settlement. The evidence does not permit a regional catalogue of diagnoses in modern biomedical terms, and it does not justify describing every early treatment as “Āyurveda.” What survives is a patchwork. Archaeology records water installations, drains, food remains, tools and settlement conditions; Buddhist and Jain texts preserve rules about illness, medicine and bodily discipline; narratives celebrate healers; and the Mauryan inscriptions speak of royal provision for treatment and medicinal plants. Classical medical compendia systematise knowledge more fully, but their surviving forms are later and layered. The historical task is therefore to reconstruct practices and institutions at the level the evidence can sustain: who cared for the sick, what resources were mobilised, how illness altered rules and work, how ascetic communities understood the body, and how towns attempted to manage water and waste.

18.2 Five evidence streams must remain separate before synthesis

No single source can stand for population health. Excavated wells or drains demonstrate infrastructure, not the prevalence of dysentery or malaria. A Vinaya rule demonstrates that a monastic community recognised a recurring practical problem, but not how every lay household treated the same condition. Jain disciplinary texts illuminate an ascetic ethic in which detachment from the body could be spiritually valued, yet they do not amount to a survey of Jain lay medicine. Aśoka’s edicts are unusually firm third-century-BCE inscriptions, but their administrative language does not automatically identify a local clinic at Vaiśālī or Campā. Finally, the Caraka and Suśruta traditions preserve sophisticated systematic medicine but cannot simply be copied backward into the age of the Buddha or Mahāvīra. The strongest reconstruction comes when independent streams converge: dense towns needed water and disposal; religious communities needed food and medicines for sick members; specialist physicians could acquire high reputation; and by the Mauryan period care and medicinal resources had entered the vocabulary of kingship.

18.3 Archaeology is strongest for environments of health, weakest for named disease

Material evidence is often indirect but indispensable. Floors, drains, wells, ring-wells, soakage arrangements, cooking installations, faunal and botanical remains, latrine-like features, skeletal trauma and residues can illuminate the conditions in which bodies lived. Yet the early historic archaeology of the study region is uneven, and published excavation reports were not designed as modern palaeopathological surveys. Human skeletal samples securely tied to particular urban phases are limited, while ring-wells can serve different functions at different sites. The safe use of archaeology is therefore environmental and

infrastructural. At Vaiśālī and Campā, durable urban installations confirm that households and builders invested in controlling water and wastewater within dense settlements. Such investment is historically relevant to health even where no physician's room or medicine chest can be identified. It also reminds us that the history of medicine is only one part of the history of bodily well-being; water access, food security, shelter and waste disposal may matter more to aggregate health than the most celebrated individual cure.

Figure 68 — Early health history requires separate control of archaeological, Buddhist, Jain and medical/royal evidence before synthesis.

18.4 Illness disrupted labour, ritual and mobility and therefore had economic effects

A sick body is also a social and economic event. Illness can remove a cultivator from seasonal work, interrupt a merchant's journey, reduce a craft household's output, require relatives to supply care, and consume stored food or cash. Monastic rules make this especially visible because ordinary discipline had to be modified when bodies failed: travel could be undertaken to obtain medicine, special foods could be allowed, and companions could be assigned to nursing. The same mechanisms must have existed outside monasteries, although direct household records do not survive. This is why health belongs within socio-economic history rather than in a separate history of ideas. Care requires time; medicines require acquisition; prolonged sickness shifts labour to others; specialist healers can charge fees; and urban density concentrates both demand and risk. The effect would not be equal across society. Wealthier households could mobilise servants, stored grain, transport and expert attention more readily than labourers or migrants whose subsistence depended on continuous work.

18.5 The professional healer is visible in literature before we can count physicians

Early Buddhist literature uses the figure of the physician, *vejja*, as a recognisable specialist, and the *Jīvaka* cycle gives unusually detailed narrative form to that profession. *Jīvaka* is associated with the Magadhan court, wealthy merchants and the Buddha's community. The stories portray diagnosis, prognosis, medicines, procedures, payment and professional reputation. They are literary narratives transmitted within monastic collections and cannot be treated as hospital case sheets. Their historical value lies elsewhere: an audience

could understand a world in which trained healers competed, fees mattered, rulers retained expert physicians, merchants sought treatment, and therapeutic skill created social capital. Jīvaka therefore provides a comparative eastern-Gangetic anchor rather than a local census for Mithilā or Aṅga. The narratives also show medicine crossing social institutions. Court, city, guild-like merchant interests and monastery can all make claims on one specialist's time. Health care was thus embedded in patronage and exchange rather than isolated as an autonomous profession.

18.6 Jīvaka's fame should not be converted into proof of a standardised medical curriculum

Later retellings often present Jīvaka as a model graduate of Takṣaśilā and then use his biography to describe a formal ancient medical university. The safer inference is narrower. Buddhist traditions remember advanced training under a renowned teacher and a career based on demonstrable therapeutic competence. Chapter 17 already distinguished teacher-centred learning from anachronistic university models; the same rule applies here. Medical expertise could be transmitted through prolonged apprenticeship, observation and practice without a bureaucratic degree system. The Jīvaka narratives also accumulated legendary features across different Buddhist recensions, including differing parentage and increasingly elaborate cures. Those variations are evidence for the growth of a healer ideal, not reasons to reject the whole tradition. What can be retained is the social type: a physician attached to royal and urban patrons, whose reputation depended on outcomes and whose knowledge was sufficiently specialised to distinguish him from ordinary household care.

18.7 Narrative surgery is evidence for an imagined therapeutic repertoire, not a modern operation report

The Vinaya cycle attributes striking procedures to Jīvaka, including treatment of a wealthy merchant with a severe head condition and the king's anal fistula. Such episodes have often been translated into modern labels such as “neurosurgery,” which is too precise for the evidence. The narratives do indicate that cutting, probing, wound treatment and other invasive procedures were thinkable components of skilled healing. Elsewhere the Vinaya regulates or prohibits certain surgical actions for monks, again showing familiarity with bodily intervention. But literary descriptions must not be converted into modern operative statistics or uncritical claims about technique. Classical Suśruta material gives surgery a much fuller systematic exposition, yet the extant text is layered and later in form. A responsible history therefore distinguishes three levels: early narrative awareness of invasive therapy, monastic regulation of procedures, and later textual systematisation. The sequence is historically significant even when it cannot yield a single date for the “invention” of surgery.

18.8 The Buddhist Medicine Khandhaka preserves a practical pharmacology of monastic need

The Bhesajjakhandhaka, the Medicine Khandhaka of the Pāli Vinaya, records repeated adjustments to illness. Among its best-known allowances are five tonics—ghee, butter, oil, honey and sugar or molasses—permitted to sick monks under storage rules. Other sections discuss medicines derived from roots and other plant parts, salts, preparations, foods and specific treatments. Parallel medicine sections occur in several other Vinaya traditions, which suggests that the management of sickness was not an incidental Theravāda concern. The rules are not a medical textbook organised by anatomy or disease classification. They are institutional law generated by practical questions: may this substance be consumed outside the normal meal time, how

long may it be stored, what may be accepted, and what procedure is permissible? Precisely because the genre is regulatory, it gives unusually concrete evidence that monastic communities repeatedly encountered illness and had to build therapeutic flexibility into ordinary discipline.

18.9 Food and medicine overlapped rather than belonging to sharply separate categories

Early monastic regulation shows that the boundary between nourishment and medicine was porous. Ghee, honey, oils, rice gruel and other preparations could be valued for both caloric and therapeutic reasons. A person weakened by vomiting or digestive illness did not need a modern distinction between “drug” and “diet” before receiving a useful intervention. This overlap matters for the broader study region, where most treatment probably occurred within households using foods, plants, oils, heat, massage, rest and other accessible resources before a specialist was summoned. It also complicates economic interpretation. Medicinal care could draw on ordinary market goods, agricultural products and gifts rather than on a separate pharmaceutical sector. Monastic rules about accepting and storing such substances show how religious institutions converted lay donations into a managed reserve for bodily emergencies. The history of health is therefore connected directly to Chapter 10’s agriculture, Chapter 12’s markets and Chapter 16’s institutional economy.

18.10 Nursing was recognised as skilled moral labour inside the Saṅgha

A famous Vinaya episode describes a monk with dysentery lying neglected in his own excrement and urine. The Buddha and Ānanda wash and move him, after which the community is instructed that monks must care for one another. The passage goes beyond a general moral command: it discusses who should tend a sick monk and what makes a caregiver competent. Suitable medicine, beneficial food, willingness to clean bodily waste, attention to changes in the patient’s condition and supportive speech all appear within the account. The historical importance is institutional. Nursing is represented as labour requiring knowledge, patience and unpleasant physical tasks, not as an automatic extension of affection. Care could fall to teacher, pupil, co-resident or ultimately the Saṅgha. This does not prove the existence of a hospital ward in early Vaiśālī or Campā. It does show that organised religious communities could transform bodily dependency into enforceable collective obligation.

Figure 69 — Buddhist monastic care could turn illness into collective duties of nursing, provisioning and temporary rule adaptation.

18.11 The monastery could redistribute resources toward sickness without becoming a hospital

Once illness activates collective obligation, food, medicine, bedding, water and labour have to be redirected. Buddhist rules allowing travel to seek medicines or suitable provisions show that the care network could extend beyond one residence. Lay donors were crucial because the Saṅgha did not produce all of its own subsistence. A sick monk therefore stood at the centre of a chain joining caregiver, donor, market, medicinal substance and monastic authority. This is an institutional economy of health. Yet it is important not to call every monastery a hospital. Purpose-built infirmaries and more elaborate medical establishments are better documented in later periods and other regions. For the early historic phase, the safest claim is that monasteries possessed rules and social mechanisms for nursing and treatment, and that these mechanisms could make them resilient communities for people who had renounced ordinary household support.

18.12 The body in Buddhist thought was both a site of suffering and an object of practical care

Buddhist teaching repeatedly treats bodily existence as impermanent, vulnerable and incapable of providing lasting security. Contemplations of body parts, illness, ageing and death can weaken attachment to the body. That doctrinal devaluation does not produce indifference to suffering. The Vinaya's medical allowances show a pragmatic middle position: the body is not a possession to be beautified without limit, but it is the material support required for practice. Food, medicine, shelter and nursing are therefore legitimate when they serve recovery and disciplined life. This distinction is historically useful because it prevents a false opposition between "religion" and "medicine." Medical practice did not need to be secular in the modern sense to be empirical and practical. A community could simultaneously interpret illness within a moral-spiritual universe and choose remedies based on observed bodily effects.

18.13 Jain asceticism placed a sharper ethical pressure on bodily treatment

Early Jain monastic literature places exceptional emphasis on *ahiṃsā*, restraint and endurance. Treatment can create ethical problems when obtaining or applying medicine harms living beings, and attachment to bodily comfort can itself be treated as spiritually dangerous. The exemplary ascetic is therefore capable of bearing heat, hunger, disease and injury without making preservation of the body the highest value. Yet the tradition is more complex than a simple prohibition on medicine. Early canonical rules and later discussions preserve circumstances in which sick mendicants may receive food or assistance, and later Śvetāmbara commentarial literature gives much fuller attention to medical procedures. For the period of Vaiśālī and Mahāvīra, the key historical point is the tension itself: a community committed to radical non-violence and detachment still had to decide what kinds of care were compatible with ascetic discipline. This is evidence about the social governance of bodies, even when it does not yield a pharmacopoeia comparable to the Buddhist Vinaya.

18.14 Jain restraint and Buddhist therapeutic flexibility should not be turned into absolute opposites

Comparing traditions can easily produce caricature: "Buddhists treated illness; Jains refused treatment." The sources do not support so simple a division. Buddhist monks were subject to restrictions and were not

licensed to pursue bodily comfort without limit; Jain texts contain exceptions, graded capacities and obligations toward sick companions. Both traditions understood the body as temporary and morally consequential. Both also confronted communities composed of people with different strength, age and health. The contrast is therefore one of emphasis and institutional elaboration. Buddhist Vinaya literature codifies a large body of medicinal allowances relatively early, while early Jain ascetic literature places more weight on endurance and *ahiṃsā*-based restraint; later Jain commentaries negotiate practical medicine much more extensively. In the Vaiśālī–Videha landscape, where Buddhist and Jain communities interacted with the same towns and patrons, these were competing answers to a shared problem rather than isolated civilisations of health.

18.15 Women's health is visible only intermittently and must not be reconstructed from silence

The early sources are overwhelmingly composed and transmitted within male-dominated institutions, so reproductive health, menstruation, childbirth and women's household care are less directly documented than their social importance warrants. Buddhist nunneries had to manage illness and bodily requirements, and wider medical traditions eventually developed substantial material on reproduction, pregnancy and paediatrics. Jain texts also preserve conceptions of embodiment and later embryological reflection. But a detailed local history of childbirth in early Mithilā or Vaiśālī cannot be recovered from these materials without speculation. The correct response to silence is not to erase women. Childbearing, lactation and care of infants necessarily shaped household labour and mortality risk; women also participated as donors, nuns, attendants and transmitters of practical remedies. These are historically secure social roles even when the techniques of a particular midwife remain unknown.

18.16 Childhood and dependency enlarged the household economy of care

Children require food preparation, protection, treatment and supervision long before they can contribute adult labour. Early medical terminology and later systematic traditions recognise childhood as a distinct therapeutic problem, while Jīvaka's name is sometimes connected in later scholarship with the field of child care. None of this allows a regional infant mortality rate to be calculated. The social implication is more basic: health care was embedded in intergenerational households. A prolonged childhood illness tied up adult labour and food; death altered lineage and inheritance expectations; successful care strengthened the continuity of the household. Religious institutions also admitted novices, creating another setting in which dependent younger bodies required discipline and support. The history of medicine therefore intersects with Chapter 7's family history: bodily dependency is one of the reasons households and institutions redistribute resources across age groups.

18.17 Occupational injury belonged to the ordinary health burden of an agrarian-craft society

Agriculture exposed bodies to cuts, falls, animal injuries, heat, waterlogged fields and repetitive strain. Metalworking added burns and sharp tools; building work added heavy loads and falls; river transport added drowning risk; warfare and policing added weapon trauma. Excavated iron knives, sickles, blades, lances and craft tools from early historic sites show the material environment in which such injuries could occur, though an artefact alone does not prove a recorded accident. Treatment of wounds, oils, bandages, cleaning and rest would therefore have been common practical knowledge. Skilled healers became especially valuable when injuries exceeded household competence. Occupational health also had a class dimension: people whose

livelihood depended on manual labour could lose income immediately when injured, while elite households could transfer tasks to servants or dependants. The body thus linked technology and inequality.

18.18 Water management at Vaiśālī belongs to health history without becoming a sanitation myth

Excavations at Vaiśālī revealed substantial architecture together with ring-wells, soakage arrangements and drains in the long early historic sequence. These installations matter because dense settlement requires repeated decisions about obtaining water and removing wastewater. They may reduce some forms of contamination or local waterlogging, but archaeological form does not reveal the microbial quality of water. Nor does a drain prove a civic health department. The safest conclusion is that urban residents invested labour and materials in managing water at household and settlement scale. That investment would have affected convenience, cleanliness, craft production and bodily exposure. It also provides a material counterweight to textual images of prosperous Vaiśālī: the city was not only an arena of assemblies and religious encounters, but a built environment whose inhabitants had to solve mundane problems of water, refuse and crowding.

Figure 70 — Urban water and drainage infrastructure can alter bodily exposure without by itself proving disease rates or a formal public-health administration.

18.19 Campā's ring-wells and brick drains show comparable urban pressures in Aṅga

The Campā excavations near Nathnagar recorded ring-wells, brick wells and brick drains in early historic construction phases, including contexts associated with Northern Black Polished Ware and later rebuilding. As in Vaiśālī, these features should be interpreted functionally before ideologically. They document investment in water supply or soakage and in the directed movement of wastewater. Campā's riverine setting did not eliminate the need for local water management; proximity to the Ganga could coexist with seasonal flooding, silt, standing water and the practical difficulty of obtaining convenient clean water inside a dense settlement. The archaeological evidence therefore supports a history of urban bodily infrastructure, not a claim that Campā possessed a modern sanitation system. This distinction is important because the same

town is richly represented in Buddhist literature. Text and archaeology can converge on urban density and institutional complexity without one being used to invent details absent from the other.

18.20 Floodplain ecology created changing health risks that cannot be diagnosed retrospectively

Mithilā, Vajji and much of north Bihar occupy riverine plains shaped by flooding, channel migration, waterlogging and seasonal pools; Campā belongs to a different but still strongly riverine Ganga environment. Such landscapes can influence water-borne disease, vector habitats, nutrition and access to settlements. Yet modern disease geography must not be projected unchanged into antiquity. Malaria, cholera, kala-azar and other historically important diseases have specific pathogen, vector and demographic histories, and ancient texts rarely permit secure identification. What can be reconstructed is exposure structure. Floods may contaminate water and interrupt food supply; drought may concentrate people around fewer water sources; standing water can support insects; heat affects spoilage; and seasonal movement alters contact networks. Health history thus requires environmental mechanisms rather than retrospective diagnosis. Chapter 1's warning that geography is capacity rather than destiny applies equally to disease.

18.21 Famine and epidemic are linked in the later Vaiśālī plague tradition, but the tradition is not a contemporary report

The famous background story attached to the Ratana Sutta describes Vaiśālī suffering scarcity, death and pestilence before the Buddha's intervention. In the Pāli commentarial tradition, crop failure and famine lead to deaths, exposed corpses and an epidemic; supernatural beings are also part of the causal narrative. This is valuable evidence for how later Buddhist tradition imagined urban catastrophe: food shortage, mortality, environmental pollution, political response and religious protection are connected in a single story. But the explanatory background is later than the canonical verses and cannot be treated as a secure eyewitness record of a specific fifth-century-BCE epidemic. The correct historical use is comparative and representational. It demonstrates that Vaiśālī became a remembered setting for collective crisis and that Buddhist narrative could integrate material and supernatural causation. It cannot supply a pathogen name, death toll or exact date.

18.22 Aśoka's second major rock edict marks a new scale of public language about medical welfare

By the third century BCE, Major Rock Edict II states that the king made provision for medical treatment for humans and animals and caused medicinal herbs, roots and fruits to be introduced where lacking; wells and trees along roads form part of the same welfare language. This is firmer chronological evidence than many literary medical narratives because it is an imperial inscription. It shows that healing resources could be represented as an obligation of kingship on a large territorial scale. Yet translation matters: older renderings sometimes speak of "hospitals," while the Prakrit is better understood as arrangements or provision for treatment. The edict therefore does not prove that hospitals stood at Vaiśālī, Campā or every Mauryan town. Its significance is institutional and political: by Aśoka's reign, medical care, medicinal plants, water and route amenities could be gathered into an explicitly royal programme of welfare.

18.23 Medicinal plants connected health to cultivation, trade and ecological knowledge

Aśoka's reference to importing and planting useful medicinal herbs, roots and fruits is important because medicines are material commodities. They must be identified, gathered or cultivated, processed, stored and

transported. The Buddhist Vinaya's lists of plant-derived remedies similarly imply practical botanical knowledge embedded in wider exchange. Forest edges, gardens, market stalls and household stores could all participate in a therapeutic supply chain. Some substances were locally common; others may have travelled with merchants and itinerant specialists. This creates another bridge between health and economic history. A healer's skill depended not only on diagnosis but on access to ingredients, while institutional communities needed donors or funds to acquire them. However, the presence of a plant name in a text does not prove its cultivation in early Mithilā or Angā. Regional archaeobotanical confirmation is required before localising a particular *materia medica*.

18.24 The market for treatment could combine fees, patronage, gifts and charity

Jīvaka stories repeatedly connect healing with payment and patronage. Wealthy patients can promise large rewards; royal command can redirect a physician's services; religious communities receive care through patronage networks. Such narratives reveal several economic models operating simultaneously. A specialist may sell expertise, a ruler may retain or command it, a donor may subsidise care, and a monastery may redistribute donated resources to sick members. Household treatment, meanwhile, may require no monetary payment at all because care is provided by kin. Early health care was therefore not a single "market" in the modern sense. It was a mixed economy of expertise and obligation. This also means access was unequal. Reputation attracts the wealthy and powerful first unless social or religious norms create alternative channels. The Vinaya's collective nursing duty is one such institutional counterweight: care for a sick monk is justified by membership in the community rather than ability to pay.

18.25 Cleanliness, excreta and bodily waste were practical problems before germ theory

The dysentery nursing episode is striking because it does not conceal excrement, urine and the physical labour of washing a patient. Monastic rules elsewhere regulate bathing, water use, latrine behaviour and cleanliness. These practices should not be redescribed as germ theory; their justifications came from comfort, discipline, purity, social decency and observed practical consequences rather than microbiology. Yet behaviour can reduce exposure even when causal theory is different from modern medicine. The same caution applies to urban drains. A society need not know bacteria to discover that standing wastewater, foul smells or contaminated living spaces are undesirable. Health history should therefore separate effective practice from explanatory theory. This avoids two opposite errors: claiming ancient people possessed modern biomedical science, or assuming that without modern theory their practices had no practical health effects.

18.26 Classical Ayurveda is essential comparative evidence but its chronology must remain visible

The Caraka Saṃhitā and Suśruta Saṃhitā are foundational witnesses to systematic Indian medicine, but both are layered works whose surviving redactions belong around the turn of the Common Era and later stages of transmission, even where they preserve older material. They provide elaborate frameworks of diagnosis, physiology, diet, pharmacology, surgery and professional conduct far beyond what the early Vinaya sets out. Their importance for Chapter 18 is therefore comparative and developmental. They demonstrate what Indian medical traditions became capable of systematising and help scholars recognise continuities in substances or therapeutic concerns. They do not license the claim that every doctrine of the classical compendia was already taught in fifth-century-BCE Vaiśālī, Mithilā or Campā. The safest language is that early Buddhist and other evidence preserves antecedent and parallel practices within the broader history from which classical Ayurveda emerged.

18.27 Medical theory and medical practice need not have developed at the same speed

People can accumulate effective remedies and procedural skills before a unified theory explains them. Conversely, a sophisticated textual theory may circulate among specialists without governing every household cure. Early Indian medicine should therefore not be forced into a single evolutionary ladder from “magic” to “science.” Buddhist, Brahmanical and Jain materials combine ritual, moral, dietary, pharmacological and observational responses in different proportions. A spell, a change of food, a plant preparation and a wound dressing can coexist without participants experiencing a contradiction. Systematic doṣa theory becomes central in classical Ayurveda, but the history of treatment cannot be reduced to the history of that theory. For the study region, this means asking practical questions first: what bodily problem is recognised, who responds, what resource is used, and what institution authorises the response? Only then should doctrinal classifications be compared.

18.28 Health inequality followed differences in food, shelter, labour and social support

The surviving texts naturally highlight kings, monks, famous physicians and prosperous urban householders. Most sick people were none of these. A landless worker, enslaved or dependent person, itinerant labourer, widow, poor cultivator or marginal household faced a different capacity to stop work, obtain nourishing food or call a reputed healer. Urban wealth could create both resources and crowding. Monastic membership could provide care unavailable to an isolated individual, but it also imposed discipline and dependence on donors. Gender and age shaped who performed unpaid care and whose illness commanded resources. Although exact mortality and morbidity rates are unavailable, these social mechanisms are historically robust. Health inequality can be reconstructed through access to food, water, rest, skilled attention, transport and supportive institutions even when diagnoses remain unknown. The body therefore becomes one of the clearest places where economic hierarchy is lived rather than merely classified.

Figure 71 — Early Buddhist, Jain and specialist-medical traditions negotiated bodily suffering through different combinations of restraint, care and treatment.

18.29 The strongest regional conclusions are infrastructural and institutional, not diagnostic

After the evidence is controlled, several conclusions are secure. Vaiśālī and Campā were dense settlements that invested in water and drainage technologies. Buddhist institutions developed explicit rules for medicine, diet and nursing, making sickness a collective organisational problem. Jain ascetic traditions negotiated a more restrictive but not absolutely uniform relationship to bodily treatment. Professional physicians were socially intelligible and could move between court, merchants and religious communities. Mauryan royal ideology publicly claimed responsibility for treatment, medicinal plants and route-side welfare. What remains uncertain is equally important: no ancient disease map can be drawn for Mithilā–Vajji–Āṅga; no population life expectancy can be calculated; no excavated ring-well identifies a hospital; and classical medical doctrines cannot be projected unchanged into earlier centuries. The history becomes stronger, not weaker, when these limits are made explicit.

18.30 Conclusion: health was produced by households, specialists, institutions and environments together

Early health in Mithilā–Videha, Vajji and Āṅga was never the product of medicine alone. Bodies depended on nutrition, water, shelter, work rhythms, household care and environmental conditions. When ordinary care failed, specialists could enter; when household support was renounced, monastic institutions had to create alternative systems of nursing and provision. Buddhist and Jain traditions show different ethical negotiations of the sick and disciplined body, while Aśoka's edict shows medical welfare entering the language of territorial kingship. Archaeology at Vaiśālī and Campā supplies the material ground beneath these texts: dense urban life required built solutions for water and wastewater even when disease itself remains archaeologically invisible. Taken together, the evidence reveals a plural health economy rather than a single medical system. Its history lies in the relationships among vulnerability, care, resources, knowledge and authority. That framework also provides the transition to Part III, where ritual, religious practice and cultural formation will be examined without separating them artificially from the bodies and institutions that sustained them.

Table 18.1 — Evidence for health, medicine and the body, and limits of inference

Evidence	What it supports	What it does not prove alone	Key references / control
Vaiśālī ring-wells, soakage arrangements and drains	Investment in water/waste management within a dense early historic settlement	Specific pathogens, disease rates, a hospital, or a municipal health department	Sinha & Roy; ASI reviews
Campā ring-wells, brick wells and drains	Urban water and wastewater infrastructure across successive construction phases	That every installation had a hygienic function or that river proximity ensured clean water	ASI 1970–75 reviews
Buddhist Bhesajakkhandhaka	Medicinal allowances, foods, storage rules and repeated institutional response to sickness	Population-wide medical practice or a complete medical theory	Horner; Sik; Zysk

Evidence	What it supports	What it does not prove alone	Key references / control
Vinaya sick-monk nursing episode	Collective obligation, skilled nursing tasks and care relationships inside the Saṅgha	A purpose-built hospital or universal lay access to care	Horner; Fish
Jīvaka narratives	Recognisable specialist physician, reputation, fees, royal and merchant patronage, invasive therapy in narrative	A verbatim case record, modern “neurosurgery,” or a standardised university degree	Horner; Zysk
Early Jain monastic rules	Ascetic valuation of endurance, ahimsā-based constraints and limited accommodations for sickness	Complete rejection of all medicine by all Jains	Deo; Stuart
Aśoka Major Rock Edict II	Third-century-BCE royal provision for human/animal treatment, medicinal plants, wells and trees	Hospitals at every Mauryan town or a specific clinic at Vaiśālī or Campā	Hultzsck
Caraka and Suśruta traditions	Later systematic Indian medicine useful for tracing mature theories and comparison	That all classical doctrines already operated unchanged in fifth-century-BCE eastern India	Meulenbeld; Wujastyk; Zysk
Vaiśālī famine/pestilence background to Ratana Sutta	Later Buddhist memory linking scarcity, mortality, pollution, political response and religious protection	A contemporary epidemiological report, pathogen identification or numerical mortality	Commentarial tradition; use with chronological caution

PART III

RELIGION, RITUAL AND CULTURAL FORMATION

Chapters 19–25

Chapter 19 — From Vedic ritual landscapes to regional religious cultures

Chapter argument. Religious change in early Mithilā–Videha, Vajji and Aṅga was cumulative and plural. Vedic ritual traditions were extended eastward and transformed in the courts of Videha; Buddhist, Jain and other śramaṇa communities then became deeply embedded in the urban and political landscapes of Vaiśālī and Campā; and Mauryan and later monumentality made some sacred memories archaeologically durable. The chapter keeps textual, archaeological and inscriptional layers separate, treats “Greater Magadha” as a debated interpretive model rather than a fixed cultural border, and rejects both a timeless regional religion and a simple replacement sequence.

19.1 Religious history must begin with overlapping practices rather than modern labels

The religious history of early Mithilā–Videha, Vajji and Aṅga cannot be reconstructed by projecting later, neatly bounded communities backward into the first millennium BCE. “Vedic,” “Brahmanical,” “Buddhist” and “Jain” are indispensable analytical terms, but each covers internal variation and long chronological development. Households could maintain rites of kinship, fertility, ancestors, protection and seasonal obligation that elite texts barely describe. Kings could patronise sacrificial specialists while also receiving renunciators and teachers. Merchants and urban householders could donate to more than one religious network. Ascetic communities themselves debated discipline, doctrine and acceptable relations with lay society. The chapter therefore treats religion as a changing field of institutions, practices, patronage and ideas. It asks how ritual authority moved eastward, how Videha became a celebrated courtly setting for Vedic and Upaniṣadic discourse, how Vajji and Aṅga became central to śramaṇa itineraries, and how later monuments materialised memories that were not necessarily monumental at the beginning.

19.2 Four evidence streams have to be controlled before they are combined

The strongest reconstruction separates textual memory, archaeology, early Buddhist and Jain traditions, and later inscriptional or monumental evidence. The Śatapatha Brāhmaṇa and Bṛhadāraṇyaka Upaniṣad are exceptionally important for Videha, but they are literary works with ritual and philosophical agendas, not annals. Archaeology can identify settlement horizons, structures, ceramics, figurines, shrines and later stupas, yet material objects rarely declare the identity of their users. Buddhist and Jain canons preserve dense place traditions for Vaiśālī and Campā, but their redaction histories require caution. Mauryan pillars, stūpa enlargements and inscriptions are firmer material evidence for the third century BCE and after, not automatic proof of an identical monumental landscape in the Buddha’s lifetime. Historical confidence rises when independent streams converge on place, chronology and institution; it falls when a later sacred biography is simply mapped onto an earlier archaeological layer.

19.3 The Śatapatha story of Videgha Māthava is a charter of ritual eastward movement

A famous passage of the Śatapatha Brāhmaṇa tells how Agni Vaiśvānara moved eastward from the Sarasvatī while Videgha Māthava and the priest Gotama Rāhūgaṇa followed. The fire reaches the Sadānīrā, a river flowing from the northern mountain, and the text remembers a time when Brahmins did not cross because the land beyond had not been “tasted” by Agni. The passage then contrasts that remembered past

with a present in which Brahmins live east of the river and cultivation is established. This is powerful evidence for how Vedic tradition conceptualised the incorporation of an eastern region into its ritual geography. It should not, however, be literalised into a story of forest fires clearing virgin land or a single invading migration. Michael Witzel’s influential reading treats the narrative as a charter of Sanskritisation and ritual orthopraxy. Even without adopting every implication of that model, the text clearly encodes a remembered boundary and its eventual crossing.

Figure 72 — Regional religious history requires separate control of Vedic texts, archaeology, śramaṇa traditions and later monumental evidence.

19.4 Sadānīrā was a symbolic threshold, but its exact modern identification remains debated

The Śatapatha passage makes the Sadānīrā separate Kosala and Videha, and later scholarship has often identified it with the Gaṇḍak or one of the river systems descending from the Himalayan foothills. Exact identification is less secure than the narrative function. The river marks a transition between an older ritual centre and a region being incorporated into the cultural world of the text. Rivers in such narratives can operate simultaneously as real geographic features, political boundaries and ritual symbols. Because north Bihar’s channels have shifted over long periods, one-to-one modern mapping should be cautious. The more durable conclusion is that the tradition locates Videha east of a significant north–south river threshold and remembers Brahmanical presence there as historically acquired rather than primordial. That is precisely why the passage matters for socio-cultural history: it preserves a memory of cultural change inside Vedic tradition itself.

Figure 73 — The Śatapatha Brāhmaṇa remembers Sadānīrā as a ritual-cultural threshold; the narrative should not be read as a literal fire-clearing or single-migration map.

19.5 Videha did not remain a peripheral recipient of western ritual authority

The later books of the Śatapatha Brāhmaṇa reverse the perspective of simple eastward diffusion. Janaka of Videha appears as a major royal patron who questions Yājñavalkya about the Agnihotra and sponsors sacrificial gatherings with substantial gifts. In one celebrated episode a thousand cows are set apart for the most learned ritual specialist, generating a contest of knowledge. These scenes depict Videha as a place where ritual authority is tested and redistributed, not merely imported. Scholars from Kuru-Pañcāla remain important, but the eastern court becomes a prestigious arena in its own right. The transformation is historically significant even if the episodes cannot be dated as court minutes. A region once remembered as outside the full reach of sacrificial orthopraxy is later represented as a centre capable of attracting, rewarding and interrogating leading specialists.

19.6 Sacrificial patronage was an economic and political institution as well as a religious act

Large sacrifices required animals, grain, dairy products, fuel, vessels, specialist labour, hospitality and gifts. The religious prestige of a Janaka therefore rested on material mobilisation as well as doctrinal knowledge. Cattle given to priests were stores of wealth and productive assets; gold attached to horns in Upaniṣadic narrative dramatizes both value and status. Sacrifice also assembled people who might otherwise be dispersed: rulers, ritualists, students, dependants and observers. Such gatherings could reinforce hierarchy, create alliances and circulate knowledge. This does not mean every household participated in elite śrauta ritual or that ritual expenditure dominated the whole economy. It means that royal sacrifice was one institutional mechanism through which surplus, prestige and intellectual competition became linked. In a socio-cultural history, the ritual field must therefore be connected to cattle, food, labour and patronage rather than treated as pure theology.

19.7 Janaka's court is remembered as a place where ritual knowledge opened into philosophical inquiry

The Bṛhadāraṇyaka Upaniṣad uses the court of Janaka of Videha as a recurring setting for encounters with Yājñavalkya and other learned figures. Questions move beyond correct sacrificial performance toward speech, mind, self, death and ultimate reality. The literary architecture is important: a royal court provides the public stage on which specialists compete, women such as Gārgī intervene in debate, and knowledge can command rewards. The transition from ritual exegesis to speculation should not be described as a sudden rejection of sacrifice. Much Upaniṣadic thinking grows through reinterpretation of ritual categories and through competition over who truly understands them. Videha's place in this literature therefore illustrates transformation within elite religious culture. It also shows why a simple binary—"Vedic west" versus "anti-Vedic east"—can obscure processes in which eastern courts appropriated, reshaped and amplified Vedic traditions.

19.8 The presence of women in elite debate is significant but does not prove general gender equality

Gārgī Vācaknavī is one of the most striking voices in the Bṛhadāraṇyaka's Janaka-cycle debates, while Maitreyī's dialogue with Yājñavalkya explores wealth, immortality and the self in a domestic setting. Their literary presence establishes that the tradition could imagine women as serious participants in philosophical inquiry. It does not establish how many women were educated, which social groups had access to such learning, or whether women could normally claim the same ritual roles as men. The contrast is instructive. Elite texts preserve exceptional female intellectual authority precisely in a social world structured by household, marriage, inheritance and gendered ritual roles. A regional history should neither erase these women nor convert their exceptional visibility into a demographic claim. Their importance lies in demonstrating that the remembered intellectual culture of Videha was more socially complex than a closed male priestly school.

19.9 Archaeology cannot excavate "Vedic religion" from a pot type

Ceramic traditions, iron objects, settlement expansion and fortifications are crucial for reconstructing the material world in which religious change occurred, but no pottery class is inherently Buddhist, Jain or Vedic. The temptation to equate a ware with a people or a doctrine is especially dangerous in the middle Ganga plain, where settlement sequences cross major textual transitions. Northern Black Polished Ware, for example, is associated with early urbanism and wide exchange, not with one creed. Terracotta figurines may reflect household devotion, play, ornament or ritual, depending on context. Fire installations likewise require functional analysis before being called Vedic altars. The archaeology of Mithilā-Vajji and Aṅga therefore contributes most securely by reconstructing population density, urban spaces, craft production, routes and later identifiable monuments. Religious identities enter only when objects, inscriptions, architecture and textual geography converge.

19.10 The rise of śramaṇa movements belongs to the same changing eastern social world

By the middle of the first millennium BCE the eastern Gangetic plain had become a major theatre of renunciant experimentation. Buddhist, Jain, Ājīvika and other teachers criticised or bypassed aspects of sacrificial authority, developed disciplines of wandering and restraint, and competed for lay support. Their emergence is inseparable from new political formations, expanding towns and mobile routes, but no single

economic cause explains their doctrines. Renunciation could reject household status while remaining materially dependent on householders. Debate could oppose Vedic claims while borrowing a shared vocabulary of karma, rebirth, austerity and liberation whose historical development is contested. The important regional point is that Vajji, Magadha and Aṅga are not peripheral in these traditions; they are core landscapes of movement, patronage and doctrinal encounter. Religious pluralisation was therefore built into the social geography of early eastern urbanisation.

19.11 “Greater Magadha” is a useful hypothesis when treated as a model rather than a fixed border

Johannes Bronkhorst has argued that the eastern Gangetic region in which Buddhism and Jainism arose preserved a cultural complex distinct from the Vedic heartland, with ideas and practices that later interacted deeply with Brahmanical traditions. The model has been influential because it takes eastern agency seriously and resists explaining every new idea as a derivative of western Vedic religion. It is also debated. Critics question how sharply the two cultural zones can be separated, how texts should be dated, and whether concepts such as karma and rebirth developed through borrowing, internal Vedic transformation or several intersecting processes. For this volume the model is best used heuristically. It draws attention to regional difference, but it does not erase the Śatapatha’s own evidence for a Vedicised Videha or the Upaniṣadic evidence for intellectual cross-fertilisation. Cultural frontiers were porous, mobile and institutionally specific.

19.12 Vaiśālī became a meeting ground for political assembly and religious mobility

Vaiśālī’s significance in Buddhist and Jain memory rests partly on its political form. The Vajjian and Licchavi environment is represented through assemblies, clan leadership, public deliberation and wealthy urban households. Such a setting created multiple channels of patronage. A teacher did not have to depend on one king; communities could receive support from merchants, courtesans, householders and corporate groups. Buddhist narratives repeatedly place the Buddha among Licchavis and at established meeting places around Vesālī, while Jain traditions connect Mahāvīra closely with the Vaiśālī–Kuṇḍagrāma zone. These textual memories should not be merged uncritically, yet together they make one point securely: the region was imagined as a dense arena of religious mobility and lay interaction. Political plurality and religious plurality need not be causally identical, but they could reinforce a social environment in which competing teachers found audiences.

19.13 Mahāvīra’s Vaiśālī association is central to Jain regional memory

Early Jain traditions associate Mahāvīra with Kuṇḍagrāma or Kuṇḍapura near Vaiśālī and identify him with the Jñātṛka/Nāya clan. Later biographical elaboration adds genealogies, dreams and political relationships, so individual details must be stratified rather than accepted wholesale. The broad regional association, however, is deeply rooted in Jain textual memory. It situates the last Tīrthaṅkara within the same north-Bihari political and urban world that is prominent in Buddhist sources. This does not mean Jainism “began” at one excavated spot that can be securely pointed out today. Sacred topography is often stabilised by later pilgrimage. The historical value lies in the repeated linkage of Mahāvīra, Vaiśālī and the wider Videha–Vajji zone, which makes Jain ascetic networks part of the region’s early socio-cultural history rather than an external addition.

19.14 Jain asceticism reorganised the moral meaning of bodily action

The Jain emphasis on *ahiṃsā*, careful movement, restraint, fasting and vigilance toward living beings gave ordinary actions—eating, walking, drawing water, lighting fires, accepting possessions—a heightened ethical charge. These disciplines were most rigorous for mendicants, while lay followers inhabited graded forms of obligation. In ecological terms, the doctrine made the body’s dependence on other life morally problematic; in social terms, it created a distinctive relationship between ascetics and donors. Renouncers reduced possessions yet required food and temporary shelter from householders. The result was not withdrawal from society but a structured interdependence. Within Vajji and adjacent regions, such networks could move along the same routes and through the same settlements used by merchants, officials and Buddhist mendicants. Religious difference therefore operated through shared infrastructure even when doctrines sharply diverged.

19.15 Buddhist Vaiśālī traditions preserve several distinct institutional memories

Buddhist literature links Vesālī with repeated visits, the Kūṭāgārasālā in the Great Wood, the gift of Ambapālī’s grove, the admission of women to the monastic order in later narrative framing, and controversies that eventually became associated with the Second Council. These events do not belong to one chronological layer, and later redaction can reshape earlier memory. Their cumulative institutional significance is nevertheless substantial. Vaiśālī is remembered not merely as a place where sermons happened but as a site of residence, donation, rule-making and community dispute. Archaeology later adds stupas, monasteries and an Aśokan pillar to this sacred landscape. The safest chronology keeps these layers distinct: early itinerant and rain-retreat traditions; subsequent organisational memory; Mauryan and post-Mauryan monumentality; and still later pilgrimage. Sacred importance was accumulated over time rather than created in a single founding moment.

19.16 Ambapālī’s gift illustrates how religious patronage could cross conventional status boundaries

The Buddhist story of Ambapālī inviting the Buddha and donating her mango grove is historically important whether or not every narrative detail is recoverable as contemporary fact. It depicts a wealthy woman outside the conventional model of a wife acting through a household patriarch as an autonomous patron capable of hospitality and land donation. The story also dramatizes competition for prestige, since Licchavi elites seek the honour of hosting the Buddha. Donation thus becomes a religious, social and political act. A grove can provide space for residence; a meal supports a mobile community; public association with a renowned teacher produces status. Such narratives remind us that early religious economies drew on more varied patrons than kings alone. They also help explain why towns with concentrated wealth and movable property were fertile settings for expanding mendicant institutions.

19.17 Campā in Aṅga was a religious meeting-place embedded in a commercial city

Campā’s early urban importance has already been reconstructed from archaeology, riverine position and textual evidence. Its religious history belongs inside that urban system. The *Dīgha Nikāya*’s *Soṇadaṇḍa Sutta* places the Buddha at Campā and depicts the eminent Brahmin *Soṇadaṇḍa* surrounded by a large following and debating what makes a true Brahmin. The episode is literary, but its social setting is revealing: a prosperous city, recognised Brahmanical status, students or dependants, public reputation and the arrival of a competing teacher. Campā is therefore not simply “Buddhist” because the Buddha visits it, nor simply

“Vedic” because a Brahmin teacher dominates local prestige. The source instead shows religious plurality and argument within an urban centre. Jain traditions also remember Campā and the Aṅga region, reinforcing the conclusion that trade routes and urban concentration supported multiple religious networks.

Figure 74 — Courtly ritual, wandering renouncers, urban/household patrons and communal institutions formed an overlapping regional religious ecology.

19.18 Religious debate was a public technology for ranking persons and doctrines

Debate appears repeatedly across the chapter’s evidence: Yājñavalkya among specialists at Janaka’s sacrifice, the Buddha disputing categories of Brahmanhood, Jain teachers defining correct conduct, and monastic communities arguing about discipline. Debate was not modern academic neutrality. Victory could establish authority, attract students, justify gifts and reorder prestige. The right to question and the ability to answer depended on social position, training and audience. Courts, parks, assembly halls, monasteries and household compounds could all become venues. The recurrence of debate across traditions suggests a shared competitive environment even when rules differed. Intellectual history is therefore also social history: doctrines moved through persons whose authority had to be performed, recognised and materially supported.

19.19 The critique of sacrifice did not cause sacrifice to disappear

Buddhist and Jain traditions are often narrated as replacements for Vedic sacrificial religion because they criticised animal killing, hereditary claims or the salvific sufficiency of ritual. Historically, the relationship was more complicated. Brahmanical ritual continued, adapted and interacted with new doctrines; Upaniṣadic speculation had already reinterpreted sacrifice from within Vedic tradition; kings could distribute patronage across competing specialists; and household ritual persisted outside the concerns of monastic texts. Religious change should therefore be described as differentiation, critique and recombination rather than a clean succession. In eastern India especially, the same social world could contain śrauta sacrifice, domestic rites, ascetic fasting, stūpa veneration, gifts to mendicants and local protective cults. The historical question is not “which religion won” at a single date but how institutions gained, lost and transformed particular kinds of authority.

19.20 The archaeological record of early Buddhism begins later than many narrative settings

A major methodological problem is the gap between the lifetime settings of early Buddhist texts and the surviving material record. Archaeologists have identified the great urban centres named in Buddhist narratives, including Vaiśālī, but securely identifiable Buddhist architecture from the pre-Mauryan period is elusive. This does not disprove early Buddhism; wandering mendicants and temporary rain retreats leave weak archaeological signatures. It does mean that a brick monastery or stūpa visible today cannot automatically be dated to the first visit described in a canonical text. The distinction is essential for Vaiśālī. Literary sacred geography may preserve early memory, while excavated monumentality reflects later institutional investment. The development from mobile community to durable complex was itself a major socio-economic transformation: land, bricks, specialised labour, maintenance and donor networks turned remembered places into built religious landscapes.

19.21 The Vaiśālī relic stūpa illustrates cumulative monumentality

Excavation of the Vaiśālī stūpa revealed successive construction phases, with an early earthen core later enlarged and encased. Archaeological interpretation has linked the monument with the Buddhist relic tradition, while later rebuilding demonstrates continuing investment. The important historical point is not that every phase can be assigned to a named event with certainty. It is that sacred memory accumulated material mass. A modest commemorative deposit could become a brick monument, attract additional construction and eventually enter a pilgrimage landscape. Monumentalisation therefore changes the economics of religion. It requires builders, bricks, land, maintenance and the coordination of donors or authorities. In socio-cultural terms, the stūpa is not only a symbol of doctrine; it is evidence that communities could mobilise resources to preserve memory in durable form.

19.22 Aśokan patronage marks a new documentary and monumental scale

The Mauryan period changes the evidentiary landscape because royal inscriptions and pillars create datable public interventions. At Kolhua near Vaiśālī, the Aśokan pillar belongs to a later material layer than the earliest Buddhist narrative traditions, but it demonstrates that the region's sacred significance had entered imperial monumental practice by the third century BCE. Aśoka's broader inscriptions articulate dhamma in ethical and administrative language rather than simply reproducing monastic doctrine. This distinction matters. Imperial support for Buddhist sites and personnel could coexist with a public moral programme addressed to wider populations. The Mauryan moment therefore should not be described as a simple "conversion of the region." It represents a new scale on which kingship, pilgrimage, inscription and memory interacted. The religious landscape became more visible archaeologically precisely because political resources helped monumentalise it.

19.23 Local cults and household religion remain the least visible part of the record

Elite texts and monumental archaeology systematically favour institutions capable of preserving words or durable structures. Most religious life probably occurred elsewhere: household offerings, ancestor rites, fertility practices, protective observances, vows, healing rituals, sacred trees, water places and local deities. Terracotta human and animal figurines from early historic sites are often invoked as evidence for popular religion, but without secure depositional context their meaning is ambiguous. A figurine may be votive, decorative, didactic or a toy. The correct response is not to exclude local religion from history but to mark

the evidentiary asymmetry. The survival of later village cults cannot be projected unchanged into the first millennium BCE; equally, the silence of canonical texts cannot be mistaken for absence. Regional religious culture was broader than the literate institutions that dominate our sources.

19.24 Sacred trees, groves and water bodies connected religion to landscape

Across Buddhist, Jain and broader South Asian traditions, groves, trees, ponds and riverbanks repeatedly serve as places of teaching, retreat, offering and memory. Such sites are socially efficient because they can lie near towns without being absorbed into dense habitation. Ambapālī's grove at Vaiśālī and Gaggara's lotus pond at Campā illustrate how named landscapes become part of religious narrative. The physical environment therefore shaped religious practice without mechanically producing doctrine. Shade, water, seasonal accessibility and distance from noise matter to mendicants; donors can endow a grove more easily than construct a large masonry complex in an early phase. Over time, remembered natural places may acquire shrines and buildings. Religious geography should thus include environmental affordances alongside political borders and urban markets.

19.25 Patronage linked religious authority to unequal distributions of wealth

Renunciant ideals often praised non-possession, yet organised religion depended on surplus held by others. Kings could give cattle and gold; merchants could provide meals and robes; prosperous householders could donate groves; women with independent resources could become patrons; communities could maintain monuments. The relationship was reciprocal but not necessarily commercial. Donors received merit, prestige, teaching or public recognition; mendicants received the material conditions of survival. These exchanges also reveal inequality. The poor could offer small gifts, labour or hospitality, but surviving texts disproportionately remember spectacular donations. A religious economy therefore redistributed some resources while reproducing distinctions of status. The question for regional history is not whether religion was "economic" but how different institutions converted material support into moral and social value.

19.26 Religious mobility depended on roads, ferries, seasons and political security

Teachers and mendicants could move only through material landscapes. The Ganga, Gandak and connected routes linked settlements while also requiring ferries and seasonal judgement. Monsoon rains encouraged more stable residence, making the rains retreat a recurring organisational feature of Buddhist monastic life. Jain mendicant discipline likewise structured movement. Political boundaries could affect safety and patronage, while commercial routes supplied audiences and food. This helps explain why the same urban nodes recur in narratives of merchants, kings and renouncers. Mobility did not make religious life placeless. On the contrary, repeated itineraries created sacred geography: a grove, hall, pond or city became memorable because communities returned to it. Routes were therefore carriers of doctrine, reputation and institutional relationships.

19.27 Language and oral transmission allowed religious communities to cross social boundaries

The region's religious traditions were transmitted for centuries largely through oral performance before surviving manuscript traditions. Vedic schools cultivated highly controlled recitation; Buddhist and Jain communities developed their own mnemonic and communal methods, often using Middle Indo-Aryan linguistic forms rather than restricting teaching to Vedic Sanskrit. Language choice affected audience and

authority. It would be simplistic, however, to describe Sanskrit as “elite” and Prakrit as “popular” in every context. Both could become learned and institutional languages, and multilingual interaction was normal. What matters historically is that different communities created reliable techniques for preserving doctrine without dependence on early monumental writing. The limited inscriptional record before the Mauryan period is therefore not evidence for a silent intellectual culture. Oral institutions were technologies of continuity.

19.28 Religious identities became more durable as institutions acquired places, rules and memories

A mobile teacher can gather followers without leaving a permanent building. A durable religious community requires more: procedures for ordination, discipline, dispute, property use, food, illness, travel, succession and remembrance. Chapters 16–18 showed how Buddhist and Jain institutions organised support and bodily discipline; the present chapter adds sacred geography and public identity. As rules accumulate and places become associated with founders, religious boundaries can harden even while interaction continues. The emergence of stūpas, monasteries, pilgrimage markers and textual canons is therefore not merely an expression of already complete religions. It is part of the process by which communities became reproducible across generations. Institutionalisation turned episodic charisma into durable social forms.

Figure 75 — Late Vedic, śramaṇa and Mauryan/post-Mauryan layers overlap; sequence does not imply disappearance of earlier practices.

19.29 Long-term continuity should not be confused with unchanging tradition

Mithilā and north Bihar later became famous for Brahmanical scholasticism, goddess traditions, Vaiṣṇava devotion, Śaiva practices, Buddhist memories and Jain pilgrimage, while Aṅga acquired its own long religious history. These later formations cannot be projected backward wholesale. The Janaka of the Bṛhadāraṇyaka is not evidence for medieval Maithil Brahman institutions; the Aśokan pillar is not proof of a fifth-century-BCE monastery in its surviving form; a modern Jain birthplace shrine does not settle the archaeology of Kuṇḍagrāma. Continuity is historical only when mechanisms of transmission can be shown. The responsible method is layered: establish the earliest secure witness, follow later additions, and distinguish remembered

antiquity from material continuity. This protects the genuine depth of regional religious history from being weakened by claims the evidence cannot sustain.

19.30 Conclusion: the region became religiously important through interaction, not isolation

The religious importance of Mithilā–Videha, Vajji and Aṅga emerged from repeated interaction among landscapes, courts, towns, householders, ritual specialists and renouncers. The Śatapatha Brāhmaṇa remembers Videha as a region incorporated into Vedic ritual geography and later portrays its king as a formidable patron and interlocutor. Upaniṣadic texts turn that courtly world into a theatre of philosophical competition. Vaiśālī and Campā then stand at the centre of Buddhist and Jain itineraries, urban patronage and institutional memory. Archaeology shows the material growth of the towns and, later, the monumentality through which sacred memories became durable. No single “conversion” explains this history. Vedic, Brahmanical, śramaṇa and local practices overlapped, argued, borrowed and competed. The regional religious culture that emerged was therefore plural from an early stage—not because boundaries never mattered, but because boundaries were repeatedly negotiated through patronage, debate, mobility and place.

Table 19.1 — Evidence for religious change and limits of inference

Evidence	What it supports	What it does not prove alone	Chronological control
Śatapatha Brāhmaṇa 1.4.1: Videgha and Māthava and Sadānīrā	Vedic memory of an eastern ritual frontier and later incorporation of Videha	A literal forest-fire migration, empty land, or precise modern river identification	Late Vedic textual tradition; literary charter
Śatapatha / Brhadāranyaka Janaka cycles	Videha as a prestigious arena of sacrifice, gifts, debate and philosophical inquiry	Verbatim court transcripts or a permanent “university”	Layered late Vedic / early Upaniṣadic literature
Early historic settlement archaeology	Urbanisation, craft, routes and the material setting of religious pluralisation	Religious identity from pottery alone	Site-specific stratigraphy
Buddhist Vesālī traditions	Repeated residence, patronage, institutional memory and dispute	That all surviving monuments date to the Buddha’s lifetime	Canonical memory with later redaction
Jain Vaiśālī–Kuṇḍagrāma traditions	Strong regional association of Mahāvīra and early Jain communities	Secure identification of every modern pilgrimage spot with a first-millennium-BCE structure	Canonical and later biographical strata
Soṇadaṇḍa Sutta at Campā	Brahmanical prestige and Buddhist debate within an Aṅga urban setting	A city-wide conversion to Buddhism	Early Buddhist literary setting
Vaiśālī relic stūpa phases	Cumulative Buddhist monumentality and resource investment	Exact dating of every phase to a named canonical event	Excavated structural sequence
Aśokan pillar / Mauryan monumental horizon	Third-century-BCE imperial participation in sacred geography	Identical monumental landscape in the fifth century BCE	Mauryan and later material evidence
Terracottas, trees, ponds and local sacred places	Possible household/local ritual landscapes and environmental settings	A named deity or doctrine without context/inscription	Interpret cautiously by context

Chapter 20 — Buddhism in the social history of Vajji and Videha

Chapter argument. Buddhism became socially durable in Vajji and Videha through overlapping networks of mobility, patronage, political encounter, gendered participation, monastic regulation and sacred memory. Vesālī provides the densest combination of discourse, Vinaya and archaeological evidence; MN 91 provides unusually direct textual evidence for the Buddha's itinerary in Videha and an encounter at Mithilā. The chapter keeps these evidence levels separate, treats council and relic traditions as historically valuable memories rather than automatic transcripts, and avoids projecting later Buddhist monumentality backward into the Buddha's lifetime.

20.1 Social history asks how Buddhism was embedded, not merely where the Buddha travelled

A social history of Buddhism in Vajji and Videha must move beyond an itinerary of famous visits. The important questions concern the people and institutions that made repeated religious interaction possible: ruling lineages, brahmins, householders, women patrons, monks, nuns, servants, cultivators and mobile specialists; the parks and halls in which teaching occurred; the food and property that sustained renunciants; and the political and legal settings in which the Saṅgha negotiated its place. Early Buddhist texts are rich in named encounters, but they are not demographic surveys. They reveal social relations selectively, through narratives shaped by doctrinal and disciplinary purposes. The chapter therefore reconstructs patterns only where several kinds of evidence converge and marks the difference between a textual social scene and an independently verified historical event.

20.2 Four evidence streams must remain separate before synthesis

The reconstruction rests on four distinct bodies of evidence. Early discourses preserve stories of the Buddha in Vesālī, the Vajjian country and Videha, including Mithilā. Vinaya texts preserve institutional memories about rules, residence, gifts, sickness, ordination and later disciplinary disputes. Archaeology at Vaiśālī preserves settlement, stūpa, pillar and monastic remains from multiple periods. Finally, later Buddhist traditions preserve memories of councils, relics and sacred geography. None should be allowed to authenticate the others automatically. A canonical place-name does not date a brick structure; an Aśokan monument does not prove that a specific sermon occurred on that spot; and a later council narrative cannot be treated as a stenographic record. The strongest history emerges from controlled comparison rather than evidentiary fusion.

Buddhism in Vajji & Videha: evidence streams

Figure 76 — Buddhist social history requires separate control of discourse, Vinaya, archaeology and later memorial traditions before synthesis.

20.3 Vajji, Videha and Mithilā should not be flattened into modern administrative geography

The labels Vajji, Videha and Mithilā belong to changing historical geographies. Early sources associate Vesālī especially with the Licchavis and the Vajjian political world, while Videha and Mithilā carry older royal and brahmanical memories and also appear in Buddhist itineraries. Historical reconstruction often treats the Videhas as connected with, or included within, the wider Vajjian political formation, but ancient usage is not perfectly uniform. Modern district, state and national boundaries are therefore unsuitable as direct equivalents. For this chapter the terms are used relationally: Vesālī is the principal urban node in the Vajjian evidence; Mithilā is the principal named city in the Videha evidence; and the intervening plains are understood as zones of movement rather than sealed cultural blocks.

20.4 The Brahmāyu Sutta gives unusually direct Buddhist evidence for Videha and Mithilā

Majjhima Nikāya 91 is one of the most important texts for this chapter because it explicitly depicts the Buddha travelling through the country of the Videhas with a large community of monks and eventually reaching Mithilā, where he stays in Makhādeva's mango grove. The narrative centres on Brahmāyu, an aged and eminent brahmin, and his student Uttara. Whatever one concludes about the literary elaboration of the story, its geography is significant: Buddhist memory did not confine the Buddha's teaching career to Magadha, Kosala and Vesālī, but located a substantial encounter in Videha itself. This textual witness is stronger than later Jātaka stories for establishing Buddhist memory of an actual teaching itinerary in Mithilā, though it still cannot be converted into an exact modern route.

20.5 Mithilā appears as a city of brahmins, householders, students and public religious reputation

The social setting of MN 91 is as revealing as its geography. Brahmāyu is represented as a learned brahmin with students, while the arrival of the Buddha draws brahmins and householders of Mithilā to Makhādeva's

mango grove. The text therefore imagines Buddhist teaching entering an already prestigious intellectual and household environment rather than an empty frontier. Reputation travels before the teacher: news of Gotama's standing prompts investigation, discussion and eventually a public audience. Socially, this is a model of religious expansion through communication networks. Buddhism does not appear by replacing brahmins and householders; it enters into argument, observation, hospitality and conversion within their existing social world. The account should not be read as evidence that all Mithilā embraced Buddhism, but it demonstrates the kind of mixed audience early Buddhist authors considered plausible there.

20.6 Brahmāyu's hospitality illustrates how lay conversion and material support could be joined

After his encounter with the Buddha, Brahmāyu is portrayed as taking refuge and inviting the Buddha and the monastic community for a meal. The narrative extends the hospitality across several days, emphasizing sustained provisioning rather than a single symbolic gesture. For social history, the important point is the linkage between doctrinal assent, household resources and the maintenance of a travelling Saṅgha. A large monastic group could not move through Videha without recurrent supplies, lodging opportunities and local intermediaries. The story does not allow the historian to calculate the cost of such support or the actual number of monks present, since large round numbers are common in religious literature. It does, however, preserve a convincing institutional logic: teaching created relationships, and relationships could be expressed materially through food, space and protection.

20.7 The Mithilā narrative is valuable precisely when its limits are stated

MN 91 cannot serve as a census of Buddhist followers in Videha. Its learned brahmin, miraculous bodily signs and highly structured conversion scene belong to a literary composition with apologetic purposes. Nor does a reference to Makhādeva's mango grove identify an excavated monastery. Yet excessive scepticism would waste the text's social information. The narrative presupposes roads, students, interregional news, public assemblies, wealthy households and the possibility that a non-local renunciant teacher could attract an audience in Mithilā. These presuppositions are historically meaningful even when individual details remain unverified. The proper use of the sutta is therefore neither literalism nor dismissal: it is evidence for how early Buddhist communities remembered their social reach into Videha and the kinds of elite and household networks through which that reach was imagined to operate.

20.8 Vesālī was a recurrent Buddhist meeting-place rather than a single-event sacred site

Vesālī occupies a different scale in the Buddhist record. Numerous discourses and Vinaya passages place the Buddha in the Great Wood at the Hall with the Peaked Roof, in or near parks, shrines and settlements around the city. Repetition matters. It suggests that Buddhist memory regarded Vesālī as a regular node of residence, teaching and institutional decision, not merely a station on the final journey. Such recurrence is socially more important than any one sermon. It implies dependable access to food, places of stay, audiences and local supporters. Later archaeology and monumentality make Vesālī's Buddhist association materially visible, but the canonical recurrence itself already points to a deeply embedded relationship between itinerant monasticism and an urban-political centre north of the Ganga.

Two regional nodes of Buddhist social life

Figure 77 — Mithilā/Videha and Vesālī/Vajji function as distinct but connected regional nodes for teachers, patrons, householders, elites and monastics.

20.9 Vesālī connected Buddhism with interregional diplomatic and intellectual traffic

Dīgha Nikāya 6 begins with the Buddha at Vesālī while brahmin emissaries from Kosala and Magadha are also staying in the city. The passage is important even if the precise business of those emissaries is uncertain. It depicts Vesālī as a place where people connected to other major states could meet, hear news and seek out religious teachers. In social terms, such traffic helps explain how Buddhist reputations and arguments travelled rapidly across political boundaries. A city used by envoys, merchants, brahmins and ruling groups could become a transmission node without being controlled by a single religious institution. Buddhism's spread depended on this broader ecology of mobility. The Saṅgha moved through routes already animated by diplomacy, commerce, kinship and pilgrimage; it did not create interregional connectivity from nothing.

20.10 The Vajjian political order forms part of the Buddhist social setting

The Mahāparinibbāna Sutta preserves a famous discussion in which the Magadhan minister Vassakāra reports Ajātasattu's intention to attack the Vajjis. The Buddha asks whether the Vajjis assemble frequently, act in concord and maintain other conditions of collective strength. The list also values established norms, respect for elders, protection of women, honouring shrines and provision for worthy renouncers. It would be anachronistic to turn this passage into a modern constitutional endorsement of "democracy." Its historical value lies elsewhere: Buddhist political reflection is articulated through features attributed to Vajjian civic life. The text assumes that assemblies, customary law, gendered security, sacred sites and support for renouncers were socially intelligible components of political durability. Buddhism here speaks within the institutional vocabulary of Vajji rather than outside it.

20.11 Buddhist monastic order and Vajjian civic order are compared, but they are not identical institutions

Immediately after the Vajjian discussion, DN 16 develops conditions for the welfare of the monastic community. The literary juxtaposition is striking: frequent assemblies, concord, respect for established

discipline and attention to seniority matter in both collective settings. Yet the Saṅgha was not a miniature Vajjian republic, and the Vajjian confederacy was not a monastic order. The comparison works because both required procedures for sustaining groups whose members had competing interests and dispersed locations. Social history should therefore focus on institutional reasoning rather than constitutional genealogy. Early Buddhists could formulate communal durability using concepts familiar from the political world around them while reworking those concepts for a renunciant community with different aims, membership rules and sanctions.

20.12 Vesālī's shrine landscape shows that Buddhism entered an already sacred city

Canonical references to the Sāranda shrine and other shrines around Vesālī are important because they prevent a false picture of Buddhism arriving in a religious vacuum. The city and its approaches already possessed named sacred places that could serve as landmarks, meeting sites and objects of collective respect. Some Buddhist narratives place teaching at such locations; other passages mention non-Buddhist renunciants active in the Vajjian country. The implication is a plural sacred landscape in which different groups occupied, interpreted and competed around existing social spaces. Later Buddhist monuments transformed parts of that landscape, but early social embedding likely depended as much on shared urban and extra-urban spaces as on purpose-built monasteries. This is why sacred geography must be reconstructed as layered rather than denominationally exclusive.

20.13 Religious competition in Vesālī was social as well as doctrinal

Buddhist texts occasionally mention rival ascetics and teachers supported in or around Vesālī. Such references are polemical and cannot be treated as neutral ethnography, yet they reveal a world in which householders and ruling groups could direct gifts, honour and attention toward multiple renunciant traditions. Competition therefore concerned reputation, patronage, ethical credibility and access to audiences as much as abstract doctrine. The Buddhist Saṅgha had to appear disciplined enough to deserve support while remaining visibly distinct from household luxury. Vinaya complaints about monastics behaving “like householders who enjoy sensual pleasures” make sense in this context: public confidence was a social resource. The rules regulated the boundary between renunciation and the material world on which renunciation depended.

20.14 Ambapālī is indispensable for the social history of Buddhist patronage

The Ambapālī episode in DN 16 presents a woman of high-status urban profession as a major independent patron. She travels in fine carriages, owns or controls a mango grove, invites the Buddha and the Saṅgha to a meal, refuses an enormous offer from Licchavi youths to surrender that privilege, and subsequently donates the grove to the monastic community. The narrative is stylised, but its social structure is unusually rich. Wealth, gender, reputation and religious generosity intersect in a single episode. Ambapālī is neither reduced to a passive devotee nor assimilated to aristocratic lineage. She acts through resources under her control. For the history of Vesālī, this matters because it broadens the patronage base beyond rulers and male household heads and shows Buddhist institutions negotiating support across socially distinctive constituencies.

20.15 The contest between Ambapālī and the Licchavis dramatizes patronage as public status

The Licchavis' attempt to acquire Ambapālī's meal invitation for a vast sum is best read as a narrative of prestige rather than a market price for access to the Buddha. Both sides understand the meal as a public act carrying honour. Ambapālī's refusal, even when the offer is rhetorically expanded to Vesālī and its revenues, reverses expected status hierarchy: a woman outside ruling lineage secures the valued opportunity before elite young men. The story therefore illuminates a social field in which religious patronage could redistribute symbolic capital. Buddhism did not erase rank, but acts of generosity allowed different patrons to compete on a moral stage whose rules were not identical to political precedence. The episode also warns historians not to treat every monetary figure in religious narrative as an economic statistic.

20.16 Donation of a grove converted private or controlled property into institutional space

When Ambapālī donates her mango grove to the Saṅgha headed by the Buddha, the narrative moves from consumption to infrastructure. A meal sustains a community for a day; a grove can support repeated residence, teaching and assembly. This transformation is central to the social history of early Buddhism. Renouncers ideally relinquished household property, yet the corporate community could depend on spaces supplied by lay patrons. Such donations created durable interfaces between monastic and lay worlds without requiring monks to become ordinary proprietors. The precise legal form of early ārāma ownership is difficult to recover from a narrative passage alone, but the institutional principle is clear: lay wealth could be redirected into a setting that supported collective religious life. The resulting space also preserved the donor's name within Buddhist memory.

Ambapālī: patronage, status and monastic space

Figure 78 — The Ambapālī narrative links control of resources, meal patronage, status competition, land donation and the creation of durable monastic space.

20.17 The alms economy linked monasteries to households every day

Large donations attract narrative attention, but ordinary food support was more fundamental. Monks and nuns depended on recurring meals, robe cloth, medicines and lodging. In a city such as Vesālī, this created daily contacts between renouncers and householders across differences of wealth and status. The

relationship was reciprocal without being a simple commercial exchange. Donors received teaching, merit, prestige or affiliation; monastics received material support while maintaining rules intended to limit accumulation and transactional dependence. This system could work only where enough households produced or controlled surplus and where movement between settlement and residence was feasible. The social history of Buddhism is therefore inseparable from the agrarian and urban economy surrounding Vesālī and the routes through Videha, even when the texts rarely describe cultivators who stood behind elite gifts.

20.18 Buddhist mobility depended on roads, ferries, villages and remembered stopping-places

The Buddhist record around Vajji is full of movement: between Magadha and Vesālī, through Nāḍikā and other settlements, into the Vajjian countryside, and onward on the final journey. MN 91 similarly imagines movement through Videha to Mithilā. These itineraries should not be converted into a single fixed road map, because river courses, seasonal conditions and textual route conventions complicate reconstruction. Their social meaning is nevertheless strong. Travelling groups required water, food, safe crossings, local knowledge and places where they could be received. Villages and small settlements were therefore as necessary to Buddhist mobility as major cities. The network was hierarchical but continuous: famous urban patrons appear in texts, while innumerable unnamed providers made the journeys possible.

20.19 Seasonal residence changed the rhythm of relations between monks and local society

The rains retreat reduced long-distance movement for part of the year and encouraged repeated residence in particular localities. DN 16 places the Buddha at Beluva near Vesālī during a rains period, while the wider corpus repeatedly associates Vesālī with established places of stay. Seasonal residence mattered socially because it turned episodic encounters into longer relationships. Lay supporters could provide food over weeks or months; monastics could teach repeatedly; disputes and health problems had to be managed within a resident community; and buildings, paths, wells or shelters became more important than they were for a single overnight halt. The development of regular residence did not abolish itinerancy. Early Buddhist institutions combined movement and anchoring, and Vesālī is one of the clearest regional places where both patterns are visible in the textual record.

20.20 Vesālī became a foundational setting in Buddhist narratives about women's ordination

The Gotamī narrative preserved in AN 8.51 and the Vinaya describes Mahāpajāpatī Gotamī travelling with Sakyan women to Vesālī, where the Buddha is staying in the Great Wood. The episode culminates in the establishment of a formal path for women to enter the homeless life. Its historical layers are debated, especially the framing of the eight weighty principles and chronological tensions noted by modern scholars. For social history, however, the location matters. Vesālī is remembered as a place where a major institutional question concerning gender, authority and membership was negotiated. The narrative makes women mobile religious actors rather than merely household donors. It also exposes the asymmetries built into the transmitted institutional order: admission to renunciation did not erase gendered hierarchy.

20.21 The bhikkhunī tradition widens the social map beyond male monastic networks

Once women's renunciation is taken seriously, early Buddhist society can no longer be described through monks and male patrons alone. Nuns required teachers, ordination procedures, residences, food, robes and protection; they interacted with laywomen and laymen and generated their own lines of seniority. The Therīgāthā preserves women's voices associated with grief, poverty, household obligations, bodily ageing and spiritual achievement, though individual poems cannot always be securely localized to Vajji or Videha. The regional significance of Vesālī lies in its role within the founding institutional memory. Historians should neither idealize that memory as evidence of complete gender equality nor dismiss it because of later redaction. It records a struggle over who could legitimately inhabit the renunciant social world.

20.22 Vinaya localization makes Vesālī a laboratory of institutional memory

The Vinaya and its analytical summaries locate several rule-origin stories in Vesālī or its vicinity. These include major narratives concerning sexual conduct, claims of spiritual attainment and other aspects of monastic discipline. It would be hazardous to assume that every rule was literally first formulated at the place named in the redacted text. The pattern is still important. Vesālī functions as a remembered setting where the expanding community encountered problems generated by wealth, reputation, sexuality, residence and relations with householders. In that sense the city becomes a laboratory of institutional memory. The stories explain why rules exist by embedding them in concrete social conflicts. The result is not a municipal archive, but it is a sophisticated record of the kinds of tensions a settled and publicly visible Saṅgha had to regulate.

20.23 Building, health and material rules reveal the practical density of monastic life at Vesālī

Vinaya passages associated with Vesālī discuss building work, water filters, walking paths, bathing or sweating facilities, illness after rich meals and the advice of the physician Jīvaka. Chapter 18 examined these materials as health history; here their institutional implication is more important. A community that needs paths levelled, drains maintained, wells protected and shared equipment regulated is no longer merely a band of solitary wanderers. Material infrastructure creates responsibilities, labour and potential disputes. It also depends on lay resources and specialist knowledge. The texts therefore show how Buddhist ideals of simplicity had to be translated into rules for collective residence. Vesālī's importance lies partly in this mundane density: religious institutions become historically visible when they have to manage space, bodies, objects and public expectations.

20.24 The Vesālī council tradition preserves memory of conflict inside an expanding Saṅgha

Theravāda Vinaya tradition places a major disciplinary settlement at Vesālī roughly a century after the Buddha's final nirvana and associates it with ten disputed practices. Modern scholarship debates the chronology, the relation between different sectarian versions and how closely the narrative corresponds to a single historical "Second Council." It is safest to treat the account as evidence for an early and durable memory of institutional disagreement centred on Vesālī. The disputed practices concern everyday monastic conduct rather than abstract metaphysics. That is socially revealing. As communities expanded across regions, differences in accepted custom, food practice, handling of resources and legal procedure could threaten shared identity. Vesālī thus remained important in Buddhist memory not only as a place of the Buddha but as a place where later Buddhists negotiated the boundaries of discipline.

20.25 The dispute over money exposes the economic problem at the heart of renunciation

Among the practices associated with the Vesālī dispute is acceptance of gold and silver, language that in Vinaya contexts includes money used in commerce. The issue reaches back to a fundamental tension. Monastics were meant to abstain from ordinary buying, selling and accumulation, yet permanent communities required food, cloth, medicine, repairs and transport. The solution was not economic independence but mediated dependence: lay supporters, stewards and institutional rules separated monastics from direct possession while keeping them within a monetising society. The Vesālī tradition therefore belongs as much to economic and social history as to ecclesiastical history. A disagreement over money was also a disagreement over how visible renunciation should remain distinct from household life once the Saṅgha had acquired durable residences and extensive patronage networks.

20.26 Relic claims turned Vajjian political identity into Buddhist civic memory

At the end of DN 16, the Licchavis of Vesālī claim a share of the Buddha's bodily relics and are said to build a stūpa and hold a festival. Whatever the precise historical sequence behind the relic-distribution narrative, it expresses an important transformation. The relationship between the Buddha and Vesālī is no longer sustained only by living visits and meals; it is converted into a claim on sacred remains and public commemoration. Political community and Buddhist memory become intertwined. A relic shrine can anchor festivals, movement, gifts and local prestige across generations. The text therefore points toward a new stage in social embedding: the teacher's mobility ends, but the sacred presence can be localized, monumentalized and reproduced through ritual.

20.27 Archaeology at Vaiśālī demonstrates long Buddhist monumentality, not a one-to-one confirmation of texts

Excavation and conservation at ancient Vaiśālī have revealed stūpa remains, brick structures, occupation deposits and the celebrated Aśokan pillar at Kolhua. Archaeologists have also identified a relic-stūpa sequence traditionally connected with the Licchavis. These remains are indispensable for demonstrating that Vaiśālī became a major locus of Buddhist monumentality. Yet the archaeological sequence spans centuries, and later enlargements or constructions cannot be assigned automatically to events narrated in early texts. The strongest conclusion is cumulative: a city already prominent in Buddhist literary memory was repeatedly marked by Buddhist building and imperial commemoration. The weakest conclusion would be that every named hall, grove or relic episode has been excavated exactly as described. Archaeology confirms durable importance, not narrative literalism.

20.28 Aśokan commemoration transformed remembered places into an imperial Buddhist landscape

The Aśokan pillar at Kolhua belongs to a later political world than the Buddha-era narratives. Its importance is precisely that chronological distance. By the Mauryan period, selected places associated with the Buddha could be monumentalized through an imperial language of pillars, stupas and pilgrimage memory. Such interventions changed how local communities and travellers encountered the past. A remembered Vajjian site became part of a wider subcontinental Buddhist geography. This process should not be projected backward: an Aśokan pillar cannot prove that a fifth-century-BCE audience stood at the same exact spot. But it shows that Vesālī's Buddhist associations had become sufficiently authoritative to attract

durable monumental investment. Social memory had moved from oral and institutional networks into stone and brick.

From itinerancy to durable Buddhist institutions

Figure 79 — Buddhist regional embedding developed through overlapping phases of itinerancy, seasonal residence, regulated community life and civic-monumental memory.

20.29 The strongest conclusions differ for Vesālī and Mithilā

The evidence is asymmetrical. For Vesālī, early Buddhist texts are numerous, Vinaya traditions are dense, later council and relic memories are strong, and archaeology preserves major Buddhist monuments. For Mithilā and wider Videha, MN 91 gives unusually explicit textual evidence for a Buddhist itinerary and an encounter with brahmins and householders, but comparable early Buddhist monumental archaeology is much thinner in the present evidentiary record. This difference must not be concealed by regional enthusiasm. It does not mean Buddhism was socially unimportant in Videha; it means the surviving kinds of proof are different. A responsible regional history therefore gives Vesālī a denser institutional reconstruction while treating Mithilā primarily through textual networks, mobility and patronage unless additional securely dated material evidence becomes available.

20.30 Conclusion: Buddhism became regional through relationships, rules, spaces and memory

Buddhism's social history in Vajji and Videha was produced by repeated relationships rather than a single act of conversion. In Videha, the Brahmāyu narrative remembers the Buddha entering Mithilā's brahmin-householder world through travel, reputation, debate and hospitality. In Vesālī, the evidence is more institutionally dense: Vajjian political discourse, elite and non-elite patronage, Ambapālī's donation, seasonal residence, women's ordination memory, Vinaya regulation, disciplinary conflict, relic claims and later monumentality all converge. Together they show how an itinerant renunciant movement could become regionally durable without ceasing to depend on lay society. The central historical process was embedding: people provided food and land; institutions regulated the resulting tensions; sacred places accumulated memory; and later monuments made selected memories materially persistent.

Table 20.1 — Evidence for Buddhism in Vajji and Videha, and limits of inference

Evidence	What it supports	What it does not prove alone	Chronological control
MN 91, Brahmāyu Sutta	Buddhist memory of travel through Videha, arrival at Mithilā, brahmin and householder audiences, hospitality	Exact route, size of the following, or archaeological identification of Makhādeva's grove	Early Buddhist discourse preserved in Majjhima Nikāya
DN 6 at Vesālī	Vesālī as a meeting-place involving Buddhist teachers and visitors linked to Kosala and Magadha	A formal diplomatic capital or permanent Buddhist institution at the Gabled Hall in the Buddha's lifetime	Early Buddhist discourse tradition
DN 16: Vajjian conditions	Buddhist representation of Vajjian assemblies, norms, elders, women, shrines and renouncers as components of political durability	Modern democracy or direct institutional derivation of the Saṅgha from Vajji	Early Buddhist political-literary memory
DN 16: Ambapālī	Female patronage, control of resources, meal giving, status competition and donation of a grove	Literal market valuation of the meal or a complete account of women's property law	Early Buddhist narrative
AN 8.51 / Vinaya Gotamī narrative	Vesālī as foundational memory for women's admission to formal renunciant life	That every transmitted rule belongs to one historical event or date	Layered canonical institutional tradition
Vinaya rule-origin stories at Vesālī	Institutional problems concerning conduct, reputation, residence, health and material life	That every rule was first formulated exactly where the redacted text says	Layered disciplinary literature
Vesālī ten-points/council tradition	Memory of disciplinary disagreement, including practices involving money and daily conduct	A fully recoverable verbatim Second Council or uncontested chronology	Sectarian Vinaya traditions; later than Buddha-era narratives
DN 16 relic distribution	Licchavi claim to relics and civic commemoration through stūpa and festival	Independent archaeological proof of the precise relic division narrative	Early Buddhist memorial narrative
Vaiśālī archaeology and Aśokan pillar	Long-term Buddhist monumentality, stūpa development, imperial commemoration and monastic occupation	Direct verification of every canonical grove, sermon or Buddha-era building	Archaeological and Mauryan/post-Mauryan layers

Chapter 21 — Jainism and the Vaishali–Videha landscape

Chapter argument. Jainism became socially embedded in the Vaiśālī–Videha landscape through disciplined ascetic mobility, repeated rainy-season residence, lay–monastic reciprocity, women’s and men’s participation, elite interaction and later sacred memory. The evidence is strongest when Jain canonical traditions, Buddhist external references, archaeology and later pilgrimage identifications are kept distinct before synthesis.

21.1 A landscape history must distinguish remembered association from demonstrable institutional presence

Jainism belongs centrally to the early religious history of Vaiśālī and Videha, but the evidence is uneven. Mahāvīra is linked by Jain tradition with Kuṇḍagrāma in the Vaiśālī–Videha zone, and later canonical material remembers repeated rainy-season residence in Vaiśālī, Vāṇijagrāma and Mithilā. Buddhist texts independently know Nigaṇṭha Nātaputta and followers of the Nigaṇṭhas in Vesālī. These strands make the region important, yet they do not justify colouring every early historic structure or settlement as “Jain.” A landscape history therefore asks where teachers, ascetics, householders and patrons interacted, how routes and seasonal residence shaped those interactions, and which claims belong to early textual memory, later sectarian biography, archaeology or modern pilgrimage identification. The result is a layered social geography rather than a single sacred map.

21.2 Four evidence streams must be controlled separately before synthesis

The first stream is Jain canonical and quasi-canonical literature: the older strata of the Ācārāṅga and Sūtrakṛtāṅga, monastic prescriptions, and the biographical and itinerary traditions preserved in the Kalpa Sūtra. The second is external evidence, especially Buddhist references to Nigaṇṭha Nātaputta and to Nigaṇṭha followers at Vesālī. The third is archaeology, which establishes the density, chronology and material character of the Vaiśālī urban landscape but rarely identifies a structure as Jain in the earliest period. The fourth is later Jain memory—commentaries, expanded biographies, pilgrimage identifications and sectarian traditions. Each stream answers a different question. A later sacred biography can preserve an older place association while also elaborating it; a Buddhist conversion story can attest rivalry while caricaturing its opponent; an urban mound can prove occupation without proving sectarian ownership.

Jainism in Vaiśālī-Videha: evidence streams

Figure 80 — Jain social history requires Jain texts, Buddhist external evidence, archaeology and later sacred memory to be controlled separately before synthesis.

21.3 The historical Mahāvīra is secure; the exact chronology and biography are not

Modern scholarship treats Mahāvīra as a historical teacher broadly belonging to the same north Indian age as the Buddha, but exact dates differ between Jain traditions and modern reconstructions. The earliest Jain disciplinary material is more useful for the character of ascetic practice than for a complete life story. Detailed accounts of conception, royal splendour, family relationships and miraculous signs belong to later biographical layers and must be read as religious memory rather than court archives. This distinction strengthens rather than weakens the history. A real renunciant movement can attract increasingly elaborate biography as communities seek to explain the authority of their teacher, locate his life in prestigious social networks and mark places with sacred significance. The historian should therefore separate the existence of Mahāvīra and early Nigaṇṭha communities from every detail later attached to his life.

21.4 Kuṇḍagrāma links Mahāvīra to the Vaiśālī-Videha zone, but its exact modern identification remains debated

The Jain biographical tradition places Mahāvīra's birth at Kuṇḍagrāma or Kuṇḍapura and describes his family as belonging to the Jñātṛ or Jñātrika Kṣatriya milieu. Hermann Jacobi, reading Jain and Buddhist place traditions together, argued that Kuṇḍagrāma was probably a modest settlement or suburb in the vicinity of Vaiśālī rather than the capital of a large kingdom. Modern identifications with particular villages near ancient Vaiśālī remain important for pilgrimage and regional memory, but archaeological proof for one exact birthplace is not decisive. The secure historical point is regional: the tradition locates Mahāvīra's natal social world in the eastern Gangetic republican/oligarchic landscape associated with Vaiśālī and Videha. The more precise the modern pin on the map, the more explicit the evidentiary caution must become.

21.5 The Jñātrika setting places renunciation inside an aristocratic and clan-based society

Jain tradition does not imagine Mahāvīra emerging from social isolation. His family is placed among Kṣatriya lineages connected with the Vaiśālī–Videha political world. Such a setting is historically plausible for an age in which aristocratic clans, household wealth, urbanising settlements and itinerant renunciant teachers interacted closely. Yet the language of “prince,” “king” and “republic” in modern retellings can flatten a more complicated hierarchy of clan heads, oligarchic councils and local notables. It is safer to speak of an elite Jñātrika environment and strong regional connections than to reconstruct a modern-style sovereign state around Kuṇḍagrāma. Renunciation acquires social meaning precisely because it is a departure from household status, inheritance, kin obligations and prestige, not because it occurs outside them.

21.6 The Pārśva-following tradition suggests a pre-Mahāvīra ascetic inheritance, but not a fully documented institutional church

A later biographical section of the Ācārāṅga states that Mahāvīra’s parents were followers of Pārśva and of śramaṇa practice. Jain tradition therefore presents Mahāvīra not as inventing renunciation from nothing but as reformulating an inherited path. Modern scholars likewise take seriously the possibility that communities associated with Pārśva preceded Mahāvīra. The evidence, however, does not permit reconstruction of a uniform Pārśva organisation across Videha before Mahāvīra, nor does it justify treating every earlier non-Vedic ascetic as Jain. The important social conclusion is more modest: eastern north India already supported renunciant alternatives and debates about restraint, karma, possession and liberation. Mahāvīra’s movement grew within that competitive field and developed a distinctive discipline and community memory.

21.7 Vaiśālī’s political and urban environment made it a natural arena for competing renunciant communities

Vaiśālī was an important Vajjian-Licchavi centre with assemblies, elite households, markets, parks and routes connecting the Ganga plain. Such conditions created audiences for multiple teachers rather than a monopoly for one tradition. Jain sources preserve kinship narratives linking Mahāvīra’s family to prominent Vaiśālī figures; Buddhist sources portray Licchavi notables moving among teachers and sects. Both bodies of literature are interested in prestige and therefore exaggeration is possible, but together they point toward a socially plural religious environment. A teacher who could attract the attention of military leaders, aristocrats, merchants and householders gained more than donations: he entered public argument about conduct, causation, violence, self-control and liberation. Vaiśālī’s importance to Jain history should thus be understood through social density and repeated interaction, not merely through a birthplace claim.

21.8 The Kalpa Sūtra preserves a powerful regional memory of repeated residence

The Kalpa Sūtra’s itinerary tradition assigns twelve rainy seasons to Vaiśālī and Vāṇijagrāma, six to Mithilā, and three to Campā and Pṛṣṭhacampā, alongside longer residence in Rājagṛha and Nālandā and shorter stays elsewhere. These numbers are among the clearest textual reasons for treating the Vaiśālī–Videha landscape as central to Jain memory. They should not, however, be converted automatically into a year-by-year contemporary diary. The text reached its received form through a long process, and scholars have disagreed over whether the list is strictly chronological apart from its explicit first and last stays. What the list securely expresses is remembered recurrence: the Jain community understood Mahāvīra’s teaching career as repeatedly embedded in these eastern cities and regions.

Mahāvīra's regional rainy-season memory

Figure 81 — The Kalpa Sūtra tradition remembers repeated rainy-season residence at Vaiśālī–Vāṇijagrāma, Mithilā and Campā–Prṣṭhacampā; the figures express regional recurrence, not a contemporary travel diary.

21.9 Rainy-season residence changed the social mechanics of an itinerant ascetic movement

A wandering ascetic can encounter many communities briefly; a rainy-season residence creates repetition. Local households learn the practical requirements of feeding ascetics, donors become familiar with teachers, disputes can be heard over time, novices can receive instruction, and lay supporters can form durable relationships with a mendicant group. The monsoon also constrains mobility and increases the ethical problem of harming small forms of life on wet ground, a concern especially resonant with Jain discipline. The social importance of cāturmāsa therefore does not depend on identifying a permanent monastery. Temporary or modest lodging could still generate dense institutional relationships. Repeated residence at Vaiśālī–Vāṇijagrāma in Jain memory helps explain how an ascetic movement could become locally rooted while preserving the ideal of non-possession and mobility.

21.10 Vāṇijagrāma should be treated as a settlement name, not automatic proof of a merchant-dominated Jain economy

The name Vāṇijagrāma has often encouraged association with traders or a commercial quarter, and such an interpretation is plausible within an urbanising Gangetic setting. Yet a toponym alone does not establish the occupational composition of its inhabitants, much less prove that merchants already formed the dominant social base of Jainism. Later Jain history contains strong mercantile traditions, but these should not be projected wholesale into the sixth or fifth centuries BCE. The safer inference is that the Vaiśālī region included settlements tied to movement, exchange and provisioning and that Jain ascetics depended on lay food and shelter within such environments. Economic embeddedness is real; the stereotype of an eternally “merchant religion” is not a substitute for evidence.

21.11 Mithilā belongs to Jain remembered geography independently of later medieval scholastic fame

The six rainy seasons assigned to Mithilā in the Kalpa Sūtra tradition deserve attention because they place Jain activity within the Videha heartland rather than only around Vaiśālī. This early association must be kept separate from the very different medieval and early modern history for which Mithila became famous as a centre of Sanskrit learning and regional Brahmanical institutions. The Jain itinerary does not identify a university, monastery complex or exact urban quarter in Mithilā, nor does archaeology presently permit a direct matching of the textual stay to a specific building. It does, however, preserve a strong claim that the regional capital or cultural centre called Mithilā lay within Mahāvīra's recurring field of activity. Jainism therefore forms part of the *longue durée* of religious plurality in Videha.

21.12 Campā and Pṛṣṭhacampā extend the Jain social horizon eastward into Aṅga

Although this chapter focuses on Vaiśālī and Videha, Campā provides an essential eastern comparison. Jain tradition assigns three rainy seasons to Campā and Pṛṣṭhacampā, while later narratives connect the city with prominent lay and female disciples. Chapter 14 established Campā as a major early historic settlement with craft, exchange and riverine connections. The Jain itinerary fits that broader urban geography without proving that Campā was dominated by Jainism. Its significance lies in the network: Vaiśālī, Mithilā, Rājagṛha–Nālandā and Campā formed part of a wider eastern corridor through which ascetics, patrons, merchants, officials and ideas moved. The social history of Jainism is therefore regional and mobile, crossing political boundaries that later historical writing often treats separately.

21.13 Buddhist references provide an external control on Jain presence at Vesālī

Early Buddhist literature repeatedly refers to Nigaṇṭha Nātaputta, the Buddhist designation for Mahāvīra, and to Nigaṇṭha followers. Such passages are polemical and cannot be read as neutral reports of Jain doctrine, yet they are historically valuable because they arise outside Jain self-description. The Siha episode in the Aṅguttara Nikāya places a prominent Licchavi general at Vesālī as a follower of the Nigaṇṭhas before narrating his shift of allegiance to the Buddha. The conversion motif naturally magnifies Buddhist success, but it presupposes something important: a recognised Nigaṇṭha teacher, elite followers and competition for patronage in the city. External rivalry thus confirms the plural religious setting already suggested by Jain regional memory.

21.14 The Siha narrative reveals competition over prestige, patronage and ethical reputation

In the Buddhist Siha story, religious affiliation is public. Licchavi notables praise the Buddha in an assembly; Siha consults Nigaṇṭha Nātaputta; after his conversion he offers a meal; rival Nigaṇṭhas then challenge the ethical legitimacy of that meal by accusing the Buddhists of accepting meat from an animal killed for them. The details belong to Buddhist narrative and should not be used to reconstruct Jain practice mechanically. Nevertheless, the episode shows how doctrines of action and non-violence could become socially visible through patronage and food. Elite allegiance affected reputation, material support and public debate. Religious competition in Vesālī was therefore not confined to abstract metaphysics: it operated through meals, households, assemblies, rumours and the moral evaluation of everyday acts.

21.15 Inter-sectarian debate sharpened identities without creating sealed communities

Jain, Buddhist, Ājīvika and Brahmanical teachers shared roads, cities, patrons and conceptual problems. They disputed karma, agency, liberation, ascetic severity and the consequences of action, but followers could listen across boundaries and sometimes shift allegiance. Texts written within one tradition routinely portray rivals in simplified terms; this is evidence of competition, not a licence to reproduce the caricature as history. A socially useful model is a crowded religious field: teachers differentiate themselves by discipline and doctrine while depending on many of the same urban and rural households. In Vaiśālī especially, sectarian identity appears as something publicly argued and maintained, not as an isolated community living apart from the wider Vajjian society.

21.16 Jain ascetic mobility transformed ordinary landscapes into ethical terrain

The Ācārāṅga's concern with careful walking, sitting, eating, drinking and handling of the environment turns movement itself into moral practice. Roads, fields, wet ground, water, plants, insects and household thresholds are not neutral background; they are places where injury may occur. An itinerant ascetic therefore experiences the landscape differently from a caravan merchant, soldier or cultivator. This does not mean that early Jain communities possessed modern ecological science, nor that non-violence automatically produced environmental conservation at a societal scale. It means that the discipline trained practitioners to see living beings and bodily movement as ethically charged. In a floodplain region of intense agriculture, seasonal moisture and dense settlement, such attentiveness would have shaped the rhythm and practical difficulty of renunciant life.

21.17 Ahimsā was a demanding discipline before it became a general emblem of Jain identity

Jain texts organise ascetic conduct around avoidance of injury to living beings, extending moral concern far beyond obvious human and animal victims. The early disciplinary emphasis is severe: harm can occur through carelessness, through instruments, through food preparation or through the actions one causes or approves. For social history, the important question is how such an ideal was negotiated between renunciants and householders who cultivated fields, cooked, traded, administered and defended communities. The existence of a radical ascetic norm does not prove that all Jain lay supporters practised it with identical intensity. Instead it created a graded ethical relationship between complete renunciation and household life, a relationship that later Jain tradition systematised in increasingly detailed forms.

21.18 Non-possession increased rather than eliminated the importance of lay support

Aparigraha and monastic restrictions on ownership are sometimes described as withdrawal from economy. Institutionally, they create a different kind of dependence. Ascetics who do not accumulate food, wealth or durable household property must obtain limited necessities from others under strict rules. The moral burden is divided: the renunciant seeks to minimise possession and attachment; the donor produces, stores and transfers the material support that makes renunciation possible. This reciprocal relation helps explain why Jainism could remain intensely ascetic while developing stable lay communities. It also cautions against confusing poverty of the monk with poverty of the movement. A community can possess few objects individually yet be sustained by socially powerful households, repeated hospitality and networks extending across towns and villages.

21.19 The fourfold community made gender and household status part of Jain institutional design

Jain tradition defines the religious community through monks, nuns, laymen and laywomen. The precise historical development of this fourfold model cannot be dated from a single text, and traditional membership numbers are not reliable censuses. Nevertheless, the institutional principle is fundamental: liberation-oriented asceticism did not erase householders; it organised relations between renunciants and lay supporters, and it recognised women on both sides of that boundary. This structure helps explain social durability. Monks and nuns carried discipline and teaching; lay women and men supplied food, shelter, protection and continuity in places where ascetics could not own households. The community was therefore neither only a monastic order nor merely a congregation of householders, but a structured field of unequal yet reciprocal roles.

Fourfold Jain community

Figure 82 — The fourfold Jain community links monks, nuns, laymen and laywomen through differentiated forms of renunciation, material support and ethical participation.

21.20 Women's renunciation is integral to the regional story, even where biographies are hagiographic

Later Jain narrative gives Candanā or Candanabālā a celebrated position as the first female disciple and leader of Mahāvīra's nuns, linking her story to Campā and to dramatic reversals of status, captivity and generosity. The narrative has accumulated hagiographic detail and cannot be treated as a contemporary biography. Its institutional memory is nevertheless significant: Jain tradition regarded a women's ascetic order as foundational, not incidental. Nuns required food, routes, teachers, lodging arrangements and lay female support, creating gendered networks that conventional political history rarely records. The presence of women in the fourfold community therefore enlarges the map of Jain social history from male teachers and rulers to households, donors, itinerant nuns and women negotiating renunciation within patriarchal society.

21.21 Lay vows adapted ascetic ethics to household life without making householders miniature monks

Later Jain texts articulate graded vows for lay followers, commonly described as lesser or limited vows in contrast with the great vows of mendicants. The fully developed schemes belong to textual histories that extend beyond Mahāvīra's lifetime, so every later detail should not be projected backward. The underlying social problem, however, is already clear: householders could not imitate wandering nudity, total non-possession or the full disciplines of mendicancy while maintaining family and productive life. Jainism endured because ethical participation could be graded. Lay restraint, almsgiving, fasting, truthfulness and limits on violence created forms of commitment compatible with household continuity. The distinction between ascetic and lay discipline was therefore not evidence of failure; it was an institutional solution to the tension between liberation and society.

21.22 Early Jain social history should not be rewritten through the stereotype of the later merchant community

Jains became conspicuous in commerce, banking, craft patronage and urban philanthropy in many later periods and regions. That history is real, but it does not follow that Mahāvīra's earliest supporters in Vaiśālī and Videha were already a socially uniform mercantile bloc. Early texts mention rulers, warriors, householders, urban elites and other groups; the material demands of alms-based asceticism could be met by different kinds of households. The rise of towns and markets certainly created conditions favourable to mobile teachers and patronage networks, yet urbanisation does not equal merchant monopoly. A chronological approach asks when particular occupational profiles become visible in inscriptions and records rather than using medieval or modern Jain prosperity to fill gaps in early history.

21.23 Political kinship traditions are evidence of how Jains remembered patronage, not transparent diplomatic archives

Śvetāmbara narratives connect Mahāvīra through his mother Trīśālā with Ceṭaka of Vaiśālī and extend a web of marriages into neighbouring ruling houses. These traditions have long been used to explain the spread of Jainism through elite kinship. They may preserve real memories of aristocratic connections, but their genealogical precision is difficult to verify externally and some accounts are clearly shaped by later sectarian interests. The safest historical conclusion is that Jain memory placed Mahāvīra within a prestigious eastern Kṣatriya network and regarded political relationships as important to the movement's success. That is different from accepting every marriage, title and alliance literally. Patronage should be reconstructed where independent textual, inscriptional or archaeological control exists, while traditional genealogies remain evidence for remembered legitimacy.

21.24 Jain ethics challenged status at the level of liberation while communities still operated inside stratified society

The Jain path locates bondage and liberation in the moral and karmic condition of living beings rather than in political rank. Renunciation can therefore relativise wealth, lineage and office: a powerful householder may depend spiritually on an ascetic who owns almost nothing. Yet it would be anachronistic to infer that early Jainism abolished social hierarchy or created modern equality. Monastic admission, lay marriage, patronage and everyday occupation still unfolded in societies structured by gender, lineage, slavery or servitude, wealth and emerging status classifications. The historically productive tension lies between

universal moral accountability and unequal social worlds. Jain communities could criticise attachment and violence while simultaneously relying on donors whose resources came from those worlds.

21.25 Canonical language records transmission history, not a verbatim transcript of Mahāvīra's speech

The Śvetāmbara canon is associated with Ardhamāgadhī and related Middle Indo-Aryan literary forms, while tradition describes Mahāvīra's teaching as accessible to broad audiences. The received language of a canon, however, reflects oral preservation, recitation, standardisation and redaction over centuries. It should not be treated as a phonographic record of what was spoken in Kuṇḍagrāma, Vaiśālī or Mithilā. For regional language history this distinction matters. The presence of an eastern Middle Indo-Aryan canonical idiom demonstrates the linguistic environment in which Jain communities transmitted scripture, but it does not allow a simple equation between one canonical language and the vernacular speech of all Videha. Religious mobility likely required accommodation across dialect zones.

21.26 Vaiśālī's archaeology supplies the urban setting but does not yet provide a secure early Jain institutional footprint

Excavations at ancient Vaiśālī document fortification, habitation levels, ceramics, coins, ring-wells, drains and later monumental remains. This material demonstrates the scale and longevity of the settlement within which Jain and Buddhist texts place religious activity. It does not, by itself, identify a fifth-century-BCE Jain monastery or prove that a particular brick structure belonged to Nigaṇṭhas. That absence must also be interpreted cautiously. Early mendicants could use temporary shelters, parks, household hospitality or structures that left no sectarian inscriptions. Archaeology is therefore most powerful here as contextual evidence: it confirms an urban and connected landscape capable of supporting repeated ascetic residence and patronage while restraining the temptation to label ambiguous remains by later religious memory.

21.27 Later pilgrimage landscapes preserve memory while also relocating and monumentalising it

Modern and medieval Jain sacred geography around Vaiśālī identifies places associated with Mahāvīra's birth and life, and pilgrimage has helped keep these associations culturally alive. Pilgrimage, however, is an active historical process. Shrines are rebuilt, routes change, names migrate, rival identifications emerge and communities choose which memories to monumentalise. A present temple can therefore testify strongly to later devotion without proving the exact location of an event centuries earlier. Rather than dismissing pilgrimage as "legend," social history asks when an identification becomes visible, who supports it, how it interacts with archaeology and how it reshapes regional identity. The Vaiśālī–Videha Jain landscape is both ancient memory and continuing historical construction.

21.28 Jainism belongs to the wider eastern Gangetic śramaṇa world, but no single cultural boundary explains everything

Theories of a distinctive eastern "Greater Magadha" have productively drawn attention to the concentration of Buddhist, Jain and other renunciant movements east of the older Vedic heartland. Jain evidence from Vaiśālī, Mithilā, Rājagṛha and Campā fits an eastern zone of intense debate about karma, rebirth, austerity and liberation. Yet such models should remain heuristic. Vedic ritual traditions were also present in Videha, rulers and teachers crossed regional boundaries, and doctrines cannot be assigned mechanically to soil types or political frontiers. The Jain landscape is best understood as an overlapping

network: ascetic mobility connected multiple cities; seasonal residence deepened local relations; household patronage tied renunciants to society; and later memory fixed selected nodes as sacred places.

Vaiśālī-Videha Jain landscape: overlapping layers

Textual geography is uneven: nodes indicate remembered association, not equal archaeological proof.

Figure 83 — The Vaiśālī-Videha Jain landscape is best modelled as overlapping mobility, seasonal residence, lay-monastic networks and remembered regional nodes rather than a single sectarian territory.

21.29 The evidence is strongest for networks and repeated association, weaker for population size and exclusive territory

Several propositions are well supported when the evidence streams are combined cautiously. Mahāvīra and Nigaṇṭha communities were known in the wider eastern Gangetic world; Vaiśālī had a substantial Jain/Nigaṇṭha presence in early religious memory; Mithilā and Campā were recurring nodes in Jain itinerary tradition; lay and ascetic relations were institutionally central; and religious competition crossed elite and household networks. Other claims remain weak: the percentage of Vaiśālī's population that was Jain, the exact location of every stay, the identification of early buildings as Jain, or a continuous line from a specific ancient site to a modern shrine. Stating these limits is not agnosticism. It allows a strong history of institutions and landscapes without manufacturing demographic precision that the sources cannot supply.

21.30 Conclusion: Jainism became regional through disciplined movement, repeated residence, lay support and remembered place

Jainism in the Vaiśālī-Videha landscape was neither a detached philosophy nor a fixed territorial church. Its social presence emerged through the movement of ascetics, the ethical regulation of bodies and possessions, the hospitality of householders, the participation of women and men, seasonal residence and competition with other teachers. Jain canonical memory places Mahāvīra repeatedly at Vaiśālī-Vāṇijagrāma and Mithilā and extends the network eastward to Campā; Buddhist sources independently attest Nigaṇṭha presence and elite interaction at Vesālī. Archaeology supplies the urban context while refusing easy sectarian labels. Later pilgrimage and biography then transformed remembered associations into durable sacred geography. The history is therefore one of layered regional embedding: movement created contact, residence created relationships, community organisation created continuity, and memory created landscape.

Table 21.1 — Evidence for Jainism in the Vaiśālī–Videha landscape, and limits of inference

Evidence	What it supports	What it does not prove alone	Source control
Ācārāṅga, older disciplinary strata	Early Jain ascetic discipline, non-violence, careful movement and renunciant practice	A complete biography of Mahāvīra or exact regional population	Primary Jain monastic text; redactional layers require control
Ācārāṅga / Kalpa Sūtra biographical traditions	Kuṇḍagrāma–Videha association, family memory and later sacred biography	Literal confirmation of every genealogy, miracle or royal title	Later biographical layers within Śvetāmbara transmission
Kalpa Sūtra rainy-season list	Repeated remembered presence in Vaiśālī–Vāṇijagrāma, Mithilā and Campā	A contemporary year-by-year itinerary or exact lodging sites	Received canonical itinerary tradition; chronology debated
Aṅguttara Nikāya 8.12, Siha	Nigaṇṭha presence at Vesālī and interaction with Licchavi elites	A neutral account of Jain doctrine or demographic Buddhist victory	External Buddhist narrative; explicitly polemical/competitive
Jain Ceṭaka and kinship traditions	Memory of aristocratic connections and political patronage	Externally verified precision of every marriage and title	Sectarian genealogical tradition; corroboration uneven
Candanā/Candanabālā traditions	Importance assigned to women's renunciation and female leadership	A fully recoverable contemporary biography	Later Jain hagiographic and institutional memory
Vaiśālī archaeology	Dense early historic urban context capable of supporting itinerant and resident religious networks	Sectarian ownership of an uninscribed structure or a Jain monastery	Archaeology establishes context; religious attribution requires direct markers
Fourfold-community ideal	Institutional linkage of monks, nuns, laymen and laywomen	Traditional membership numbers as historical census	Community ideal preserved and elaborated across Jain textual history
Modern/medieval pilgrimage identifications	Continuing regional memory and sacred-place formation	Exact ancient topography solely from a present shrine	Useful for reception history; requires archaeological and textual control

Chapter 22 — Śaiva, Śākta and Vaiṣṇava transformations

Chapter argument. Between the late ancient and early medieval centuries, Śaiva, Śākta and Vaiṣṇava traditions became increasingly visible in Mithila, Vajji and Aṅga through image installation, temples, ritual specialists, patronage, sacred water and pilgrimage. The transformation was cumulative rather than a single conversion: Buddhist, Jain, Vedic, household and local practices continued within a poly-religious landscape. Regional claims are therefore tied to inscriptions, sculptures, architecture and securely controlled textual comparison rather than inferred from later sectarian prestige.

22.1 Transformation is a historical process, not a switch from one religion to another

Śaiva, Śākta and Vaiṣṇava traditions became increasingly visible in the religious landscape of eastern India between the late ancient and early medieval centuries, but the process cannot be described as a single conversion from “Vedic religion” to “Hinduism.” Sacrifice, household ritual, local cults, Buddhist and Jain institutions, image worship, temple patronage and ascetic traditions overlapped. New forms acquired monuments, specialists, texts and donors at different speeds. The historian must therefore ask when a deity, ritual or institution becomes visible in a particular evidence stream, who supported it, and whether the surviving material represents a local community, a travelling object, an elite foundation or a later reuse. The central argument of this chapter is that regional religious change occurred through institutional thickening: images, shrines, endowments, ritual experts and sacred places accumulated around older social landscapes rather than replacing them in a single chronological break.

22.2 Four evidence streams must be kept separate before they are combined

The first evidence stream is epigraphy: inscriptions can identify donors, rulers, deities, installations, tanks, temples and occasionally ritual specialists, but survive unevenly. The second is archaeology and art history: sculptures, architectural members, temple foundations and reused images can demonstrate material cult, yet often lack secure excavation context. The third is textual: Purāṇic, Āgamic, Tantric and sectarian literature records sophisticated ritual and theological systems, but the date and place of a manuscript or recension need not equal the date and place of the practices it describes. The fourth is later sacred memory, including living temples, pilgrimage claims and relocated images. Such continuity is historically important but cannot automatically date the beginning of a cult. Only after controlling these streams separately is it legitimate to reconstruct a regional transformation.

Evidence before synthesis

Figure 84 — Evidence for Śaiva, Śākta and Vaiṣṇava transformation must be separated into inscriptional, material, textual and archaeological streams before regional synthesis.

22.3 The Gupta and post-Gupta centuries intensified iconic and temple-centred worship

Across north India, the Gupta and post-Gupta centuries saw increasingly durable forms of deity installation, image patronage and temple building. Viṣṇu, Śiva, Devī and other deities had much earlier textual histories, but their material presence became more archaeologically visible through icons, shrines and inscriptions. This visibility should not be mistaken for the birth of the gods themselves. It marks a change in institutional form: divinity could be made present in consecrated images and fixed sacred buildings that required maintenance, ritual service and social investment. In eastern India the process unfolded unevenly and interacted with powerful Buddhist and Jain establishments. The result was not a uniform Brahmanical landscape but a denser field of religious institutions in which donors could support more than one tradition and sites could accumulate multiple layers of sacred use.

22.4 Śaivism was not one organisation but a family of ritual and theological formations

The label Śaiva covers practices ranging from worship of the liṅga and anthropomorphic forms of Śiva to ascetic, initiatory and Tantric systems. Early medieval inscriptions and textual research show the growing importance of Śaiva teachers, lineages and temple institutions across much of South Asia. Alexis Sanderson's influential formulation of a "Śaiva Age" draws attention to the exceptional reach of Śaiva ritual specialists and scriptures between roughly the fifth and thirteenth centuries. For Mithila, Vajji and Aṅga this macrohistorical model is useful only when tested against local evidence. A regional Śiva image or shrine supports Śaiva presence; it does not prove that a particular initiatory school operated there. The chapter therefore distinguishes broad Śiva worship from specific sectarian systems unless inscriptions or texts provide firmer identification.

22.5 Śaiva institutions connected renunciation, temple ritual and political patronage

Śaiva traditions could speak simultaneously to ascetics, householders and rulers. Renunciant prestige gave some Śaiva specialists an authority distinct from ordinary temple priesthood, while temple cult created regular ritual obligations, public festivals and durable sacred property. Royal and elite patrons could sponsor liṅgas, temples, tanks or teachers as acts of piety and political representation. These relationships were not merely ideological. A shrine required stone or brick, artisans, ritual materials, water, access routes and people responsible for daily service. Patronage could therefore bind religious institutions to agrarian and urban economies. Early medieval Bihar's documented Śaiva topography shows that Śiva worship was distributed across multiple localities rather than confined to one court. For this volume, the important social fact is the multiplication of supported nodes, not a claim that every village or ruler became exclusively Śaiva.

22.6 The liṅga is a ritual object whose history cannot be reduced to a modern symbol

The liṅga became one of the most recognisable material forms of Śiva worship. Historically, however, it should be analysed through installation, ritual use and site context rather than through a single universal explanation. A consecrated liṅga establishes a focus for offerings, bathing, circumambulation and priestly service; a portable or displaced liṅga has a different archaeological history. Multi-faced liṅgas and anthropomorphic Śiva images further show that aniconic and iconic modes were not opposites. When early medieval remains in Bihar or Mithila include liṅgas, they indicate ritual investment in Śiva, but dating must depend on associated architecture, inscription, style or excavation. Living worship around old stones may preserve continuity, may represent revival, or may combine both. The historian must leave these possibilities open where context is weak.

22.7 Śākta history requires distinguishing goddess worship from later formal Śākta systems

Female divinities appear in Vedic, epic, local and pan-Indian traditions long before the consolidation of formal Śākta theology. The early medieval centuries nevertheless transformed the scale and organisation of goddess worship. Durgā as Mahiṣāsuramardini, Pārvatī/Umā, Cāmuṇḍā, the Mothers and other forms became prominent in sculpture and sectarian texts, while Tantric traditions developed increasingly elaborate understandings of divine power, mantra and ritual. It would be methodologically unsafe to call every ancient female figurine “Śākta” or to infer a mature Tantric system from a single goddess image. The stronger inference is that goddess-centred cults became materially and theologically more visible and interacted with Śaiva, Buddhist and local traditions. Eastern India later became especially important for such interactions, making careful chronology essential.

22.8 The Devīmāhātmya helped articulate a goddess who could absorb multiple divine powers

The Devīmāhātmya, embedded in the Mārkaṇḍeya Purāṇa and generally assigned to the early centuries of the first millennium's latter half, presents Devī as a supreme power whose manifestations defeat cosmic threats. Its theological importance lies partly in synthesis: diverse goddess forms are related within a larger conception of one sovereign female divinity. The text does not document worship at a named Mithila or Aṅga site, so it cannot be used as a local gazetteer. It does, however, illuminate the conceptual environment in which images of Durgā, Cāmuṇḍā and allied forms could be understood within expanding goddess

traditions. As sculptures appear across eastern India, textual and material histories can be compared without assuming that one directly caused the other.

Transformation, not replacement

Overlapping practices could coexist for centuries.

Figure 85 — Early-medieval religious transformation is modelled as institutional thickening and overlap, not a single conversion line from earlier ritual to three mutually exclusive sects.

22.9 Goddess images reveal public materialisation, not simply private belief

A stone Maḥiṣāsūramardīnī or Cāmuṇḍā image required an artisan, a patron, a chosen iconographic programme and some intended setting. Even when that setting is lost, the object is evidence of organised material production. Pāla-period Bihar is particularly rich in images of both Buddhist and Brahmanical deities, including fierce and benign goddess forms. Such plurality cautions against assigning entire dynasties or regions a single religious identity. Sculptures also circulated after their original installations collapsed: they were reused in later temples, placed under trees, recovered from ponds or transferred to museums. Their present location therefore cannot be equated automatically with their original cult centre. Provenance, style, inscription and local archaeological context must be considered together.

22.10 Śākta and Śaiva traditions often intersected rather than occupying separate worlds

Many goddess traditions developed in close relation to Śiva. Pārvatī and Umā appear as consort figures; Durgā and Cāmuṇḍā can be integrated into Śaiva mythic and ritual systems; later Tantric corpora create even more complex relations between Śiva and Śakti. This interweaving makes modern denominational boxes misleading when applied too rigidly to early medieval evidence. A temple complex might contain Śiva, goddess, Gaṇeśa and other images; a patron could honour several forms; a ritual specialist might participate in a system that modern catalogues divide between “Śaiva” and “Śākta.” The correct historical question is therefore not which label exclusively owned a site, but how particular divine forms, ritual practices and institutions were assembled at that site over time.

22.11 Vaiṣṇava transformation joined older Viṣṇu traditions to image, temple and avatāra devotion

Viṣṇu's Vedic presence and the growth of Nārāyaṇa, Vāsudeva-Kṛṣṇa and avatāra traditions long predate the early medieval period. What changes visibly in archaeology is the density and institutional setting of Vaiṣṇava images and temples. Four-armed Viṣṇu figures with conch, discus, mace and lotus, images of Varāha or Narasiṃha, and complex stelae with attendants and personified attributes materialise a theological world in durable form. The temple creates recurring service and a public point of access, while royal or elite inscription can attach patronage to a named deity. This does not mean devotion was previously absent; it means the evidence for organised cult becomes more concrete. Eastern Indian sculpture demonstrates that Vaiṣṇava imagery belonged fully to the Pāla-period artistic world alongside Buddhist and Śaiva-Śākta production.

22.12 Aṅga's Mandar Hill provides a rare inscriptional anchor for regional Vaiṣṇava patronage

Mandar Hill in the wider Aṅga-Bhagalpur zone is especially valuable because a seventh-century Later Gupta inscription associated with Ādityasena links royal piety to a Viṣṇu/Narahari installation and to sacred water infrastructure created by the queen. Unlike a free-floating sculpture, an inscriptional record can connect deity, patron and place. The evidence demonstrates a Vaiṣṇava foundation in the Mandar landscape and shows how image installation, kingship and a tank could form part of one sacred project. It does not prove that Mandar was exclusively Vaiṣṇava: the hill accumulated Jain and other Hindu associations as well. Precisely this layered character makes it a strong case study for regional transformation through addition rather than replacement.

22.13 Sacred water, temple patronage and kingship formed a linked social technology

The Mandar evidence also reminds us that religious patronage extended beyond the sanctum. Tanks, wells, approach routes and settlement resources shaped access to sacred sites. A ruler or royal woman who sponsored water infrastructure participated in both piety and public utility, although the balance between these motives cannot be measured from inscriptional praise alone. In a monsoon environment, a tank could support ritual bathing, visitors and local water needs. Temples likewise generated movement of artisans, priests, donors and pilgrims. Religious institutions should therefore be placed inside material landscapes. The social history of Vaiṣṇavism, Śaivism or Śāktism cannot be written only from theology; it must include the built environment that made repeated worship possible.

22.14 Pāla political history does not equal a Buddhist monopoly on religious life

The Pāla rulers are famous for major Buddhist institutions, but the religious landscape of Bihar and Bengal under and around Pāla power was markedly plural. Brahmanical images, temples and grants coexisted with Buddhist monasteries, and regional rulers and elites could support different traditions. Birendra Nath Prasad's archaeological synthesis emphasises poly-religiosity rather than a sequence in which one religion simply replaces another. This matters for Mithila and Aṅga because Pāla-period artistic style is often encountered through both Buddhist and Hindu sculpture. A "Pāla image" is an art-historical and chronological description, not a statement that its deity is Buddhist. The same workshops or artistic conventions could serve patrons with different religious commitments.

22.15 Art-historical style can connect a sculpture to a region and period, but not reconstruct its whole institution

Susan Huntington's study of the Pāla-Sena schools remains fundamental for understanding eastern Indian stone and metal sculpture. Stylistic analysis can identify regional conventions, chronological development and relationships among images, especially when compared with dated works. Yet style alone cannot tell us who worshipped an image, how often, under what economic arrangements or whether the image stood in a large temple, a smaller shrine or another setting. This limitation is particularly important for sculptures reported from villages without controlled excavation. They are real evidence for artistic and cultic production, but their institutional biography may be partly lost. A socio-cultural history must therefore combine art history with settlement archaeology, inscriptions and later documentation without allowing one evidence type to carry conclusions it cannot support.

22.16 Mithila's surviving medieval sculptures show plurality rather than a single sectarian landscape

Published surveys of Mithila's art and archaeological discoveries record images of Viṣṇu, Śiva-Pārvatī, Gaṇeśa, Durgā/Cāmuṇḍā, Sūrya, Buddhist deities and other forms at sites across the region. Many are assigned broadly to Pāla-Sena or later medieval centuries, although individual datings require specialist review. The strongest regional conclusion is not that one cult "won," but that multiple iconographic traditions were materially established. A cluster of images at a site may indicate a temple complex, successive shrines, reuse or collection from the surrounding area; without excavation these alternatives remain open. This plural material record also warns against reading later literary or sectarian prestige backward as exclusive religious dominance.

22.17 Recent recoveries from ponds and fields demonstrate both archaeological richness and loss of context

In north Bihar, old stone images continue to be recovered accidentally during pond cleaning, cultivation and construction. Such finds can greatly expand the known corpus, but accidental discovery usually destroys stratigraphic context. A sculpture identified as Pāla or Karnata-period may still be datable stylistically, yet its original building and associated deposits may be unknown. Modern villagers may begin worship immediately, while museums and archaeologists seek conservation. This contemporary process is itself historically revealing: ancient objects can acquire new sacred biographies. For the present chapter, however, accidental finds are used cautiously—as evidence that early-medieval religious material survives widely, not as proof that the exact recovery spot was an original temple.

22.18 Vaiṣṇava images in Bihar demonstrate sophisticated iconographic production and patronage

Museum collections preserve substantial Pāla-period Vaiṣṇava sculpture from Bihar, including large bronzes and black-stone stelae. The Metropolitan Museum's early ninth-century bronze of Viṣṇu flanked by personified attributes and its later Pāla stone images illustrate the technical and theological sophistication of this production. Such objects imply patrons able to commission costly work and artisans trained in precise iconographic conventions. Their significance is broader than aesthetics: an image structured ritual attention, identified a divine form and helped make sectarian affiliation publicly legible. Yet museum provenance is sometimes only "Bihar," so these objects cannot be assigned specifically to Mithila, Vaiśālī or Aṅga unless

find history permits. They establish a regional artistic environment against which securely local finds can be compared.

Figure 86 — Selected regional anchors show different evidentiary strengths: Mithila’s sculptural plurality, Vaiśālī’s layered sacred landscape, Aṅga–Mandar’s inscriptional Vaiṣṇava anchor, and the wider eastern Bihar corridor.

22.19 Image installation created durable obligations of care

A consecrated image is not merely a representation. In temple-centred traditions it is bathed, dressed, fed, adorned, awakened, put to rest, carried in procession or approached through vows and offerings according to local and textual prescriptions. This ritual life creates recurring needs for water, flowers, food, lamps, textiles, metal vessels and human labour. Consequently, the spread of image worship also has an economic history. Priests, gardeners, potters, oil suppliers, musicians and donors may become connected to a shrine even when inscriptions preserve only the elite patron. The institution converts episodic gift into repetitive service. This is one reason temple cult could become socially durable: it embedded theology in routines of material provisioning.

22.20 Temple growth changed the spatial organisation of religious life

A monastery, sacrificial ground, household shrine and temple organise space differently. The temple establishes a fixed divine centre with thresholds, circumambulation, restricted and public zones, and often an associated settlement environment. In early medieval eastern India, temple remains are much less uniformly preserved than sculpture, partly because brick structures deteriorate and later rebuilding obscures earlier phases. Where architectural fragments survive, they can reveal the scale and aesthetic programme of patronage. Where only images survive, the original building must not be imagined beyond the evidence. Even so, the wider transformation toward fixed cult places encouraged more regular pilgrimage, seasonal gathering and local identification with a deity or sacred site.

22.21 Sectarian texts and actual village practice operated at different levels

Āgamas, Tantras and Purāṇas can specify complex initiation, mantra, diagram, temple and worship systems. Their sophistication is indispensable for intellectual history, but local practice need not reproduce a text completely. Ritual specialists select, adapt and transmit procedures; householders participate at different

levels; local deities can be identified with wider divine forms without losing distinctive traditions. Conversely, practices poorly represented in surviving texts may have been socially important. The historian should therefore resist two opposite errors: treating normative texts as exact ethnography, or dismissing texts because practice was diverse. The relationship is better understood as a repertoire from which institutions drew authority and technique.

22.22 Tantric transformations linked body, mantra, deity and power in new ritual configurations

Early medieval Tantric traditions, especially Śaiva and Śākta systems, developed powerful ritual technologies centred on initiation, mantra, visualisation, maṇḍala, the ritual body and forms of divine power. Their influence extended well beyond small esoteric groups because ritual specialists could serve rulers and temples, and because Tantric elements entered broader worship. Eastern India later became a major field of interaction among Śaiva, Śākta and Buddhist Tantric traditions. Yet the regional evidence for any specific school in Mithila, Vaiśālī or Aṅga must be demonstrated rather than assumed from eastern India as a whole. The safe conclusion is that these areas participated in a wider cultural zone in which Tantric forms became increasingly influential, while local institutional histories remain unevenly documented.

22.23 Śākta power should not be reduced to a story of “tribal absorption”

Older scholarship often explained goddess traditions through a simple model in which Brahmanical religion absorbed supposedly primitive or tribal mother goddesses. Such models can obscure agency, chronology and the complexity of religious exchange. Local goddesses, village protectors, elite temple goddesses and textual Devī forms may interact without fitting a one-way ladder from “folk” to “high” religion. In Mithila and Aṅga, later goddess centres can preserve local names and ritual features while also participating in Sanskrit myth and Tantric theology. The historical task is to trace specific connections where evidence permits. A regional goddess image with identifiable iconography is one datum; a later pilgrimage tradition is another. Neither should be forced into an evolutionary scheme unsupported by evidence.

22.24 Vaiṣṇava avatāra theology allowed regional landscapes to connect with pan-Indian narratives

The avatāra concept gave Vaiṣṇava traditions a powerful way to locate cosmic narratives in particular places. Narasiṃha, Varāha, Rāma and Kṛṣṇa could be represented in sculpture and associated with local sacred geography. Mandar’s Narahari association is an especially important regional example because inscriptional evidence links the deity with a royal foundation. Other local claims, especially those first documented much later, require separate dating. Pan-Indian narrative does not erase locality; rather, locality can gain wider prestige by being incorporated into a shared mythic world. This process helps explain how pilgrimage networks grow: a hill, tank or temple becomes simultaneously local infrastructure and a point within a larger sacred map.

22.25 Religious patronage was not mechanically determined by dynastic identity

Historians often label rulers “Buddhist,” “Śaiva” or “Vaiṣṇava,” but royal patronage could be broader than personal initiation or devotional preference. A ruler might support Brahmins, monasteries, temples, teachers and public works for different political and religious reasons. Queens, ministers, feudatories, merchants and local elites also acted independently. The Mandar record itself gives a royal woman a visible

role in sacred water patronage. In Pāla-period eastern India, the coexistence of Buddhist and Brahmanical institutions makes dynastic labels especially inadequate as descriptions of society. Religious transformation should therefore be mapped through actual grants, objects and sites rather than inferred automatically from the ruler's conventional identity.

22.26 Gender appears in patronage, goddess theology and ritual participation in different ways

The rise of goddess traditions does not by itself demonstrate increased social power for women. Divine femininity and women's legal or economic position are separate historical questions. Nevertheless, women appear in religious history as patrons, household ritual participants, ascetics and members of pilgrimage communities. Royal women could fund tanks or temples; household women could sustain vows and domestic worship; goddess theology could articulate female divinity in extraordinarily powerful terms. These dimensions intersect but should not be collapsed. A strong Devī cult may coexist with patriarchal social institutions. Conversely, an inscription naming a female donor provides concrete evidence of agency even when theological texts say little about ordinary women.

22.27 Religious specialists became mediators between textual systems and local society

Priests, ascetics, teachers, temple managers and ritual experts translated broad traditions into local institutions. Their work included consecration, daily worship, calendrical rites, teaching, dispute, healing rites, pilgrimage guidance and maintenance of sacred property. Some specialists belonged to hereditary communities; others to initiatory or monastic lineages. Surviving evidence rarely lets us reconstruct the full occupational structure of a single Mithila or Aṅga temple in this period. Nevertheless, the growth of specialised ritual systems implies social roles that could persist beyond individual patrons. Religious transformation therefore involved professional and institutional continuity as much as theological innovation.

22.28 Poly-religiosity is a better model for early medieval Bihar than a zero-sum contest

Archaeological study of Bihar and Bengal between roughly 600 and 1200 CE shows Buddhist, Brahmanical and Jain sites existing in overlapping landscapes. Competition for patronage was real, and some institutions declined while others expanded, but coexistence was common. Images and architectural remains indicate that Śaiva, Śākta and Vaiṣṇava cults did not require the immediate disappearance of Buddhist or Jain practice. Nor were the Brahmanical traditions themselves a single bloc. This model is particularly appropriate to a region already shaped by the earlier Buddhist and Jain histories of Vaiśālī and Aṅga. The early medieval transformation added new densities of temple and image-centred worship to an already plural religious environment.

How traditions became durable

Figure 87 — Sectarian traditions became socially durable through linked processes of patronage, materialisation, ritual specialists, public practice, and the continued repair or reuse of sacred objects and places.

22.29 The evidence is strongest for material and institutional visibility, weaker for population percentages

By combining inscriptions, sculpture, architectural remains and comparative texts, several conclusions are robust. Śiva, Viṣṇu and goddess cults were materially established in early medieval Bihar; Mithila preserves a diverse corpus of Brahmanical imagery; Mandar offers a specific seventh-century Vaiṣṇava patronage anchor; and wider eastern Indian religious life was poly-religious. Much weaker are claims about what percentage of the population followed each sect, whether particular villages were exclusively Śaiva or Vaiṣṇava, or how quickly household belief changed. Archaeology preserves durable objects better than private devotion. The chapter therefore speaks of expanding visibility and institutionalisation rather than demographic conversion.

22.30 Conclusion: Śaiva, Śākta and Vaiṣṇava traditions transformed the region by building durable institutions into an already plural landscape

The major transformation was not the sudden arrival of three fully formed religions. It was the progressive materialisation and institutionalisation of related but distinct traditions through images, temples, sacred water, ritual specialists, texts, patronage and pilgrimage. Śaiva networks linked ascetic authority and temple service; goddess traditions expanded through powerful iconographies and Tantric-theological synthesis; Vaiṣṇava cults connected established Viṣṇu-Nārāyaṇa traditions with temples, avatāra images and regional sacred places such as Mandar. Mithila's sculpture record and the broader archaeology of Bihar show plurality rather than monopoly. The social history that follows from this evidence is therefore one of layered sacred landscapes: older rites, Buddhist and Jain institutions, local cults and new Brahmanical temple formations interacted, competed, borrowed and endured. Chapter 23 can now examine how these accumulated traditions turned rivers, hills, ponds, routes and settlements into a more densely articulated sacred geography.

Table 22.1 — Evidence for Śaiva, Śākta and Vaiṣṇava transformations, and limits of inference

Evidence	What it supports	What it does not prove alone	Source control
Ādityasena/Mandar Hill inscription, 7th c.	Named royal Vaiṣṇava/Narahari patronage and sacred-water works in the Aṅga-Bhagalpur zone	Exclusive Vaiṣṇava control of Mandar or the beliefs of the whole population	Epigraphic anchor; later sacred layers must be separated
Pāla-period Viṣṇu sculpture from Bihar	Sophisticated Vaiṣṇava iconographic production, costly commissions and wider regional cult	A specific Mithila/Vaiśālī/Aṅga provenance when museum findspot is only “Bihar”	Use dated/provenanced objects where available
Śaiva inscriptions and shrine distribution in early medieval Bihar	Widespread Śiva-oriented patronage and institutional nodes	Presence of one uniform Śaiva sect or identical ritual at every site	Macro-regional topography requires local checking
Mithila sculptures: Viṣṇu, Śiva-Pārvatī, goddess forms and others	Material plurality of Brahmanical cults in the medieval landscape	That every recovery point is an original temple or that one cult dominated the region	Many finds lack controlled excavation context
Devīmāhātmya and later goddess literature	Theological consolidation of Devī and a framework for powerful goddess forms	Direct proof of worship at a named Mithila or Aṅga site	Textual history and local cult history must be correlated, not equated
Śaiva/Śākta Tantric corpora	Initiatory, mantra and ritual systems influential in early medieval religious culture	Automatic presence of a named Tantric school wherever Śiva or Devī images occur	Specific lineages require textual, inscriptional or other local evidence
Archaeology of Bihar–Bengal, c. 600–1200	Poly-religiosity, coexistence and competition among Buddhist, Jain and Brahmanical institutions	A simple replacement sequence or demographic percentages	Site-by-site chronology remains essential
Later living temples, pilgrimage claims and reused ancient images	Continuing sacred memory and new biographies of old objects	The foundation date of a cult without earlier evidence	Continuity, revival and reuse must remain separate possibilities

Chapter 23 — Sacred geography

Chapter argument. Sacred geography in Mithila, Vajji and Aṅga was produced cumulatively through remembered narratives, repeated movement, water and route infrastructure, monuments, patronage and later pilgrimage. The chapter separates textual, archaeological, epigraphic and later devotional evidence so that modern holy places are not projected backward as unchanged ancient sites. It then reconstructs how rivers, groves, ponds, hills, cities and monastic complexes became connected into layered and often poly-religious regional landscapes.

23.1 Sacred geography is made through historical practice, not discovered as a timeless map

Sacred geography is the organisation of space through remembered events, ritual acts, institutions, routes and material markers. A river may be physically ancient while its association with a particular deity, teacher or pilgrimage circuit is much later. A hill can acquire several religious meanings in different centuries, and a pond can function simultaneously as water infrastructure, a ritual bathing place and a landmark in narrative memory. The history of Mithila, Vajji and Aṅga therefore requires a layered method. It is not enough to collect modern holy places and project them backward. Nor should later pilgrimage be dismissed as mere legend. Sacred landscapes are historical achievements: communities select places, return to them, invest in them, argue over them, rebuild them and connect them to wider narratives. The central question is not simply which places were sacred, but when, to whom, through what evidence, and with what social consequences.

23.2 Four evidence streams must be dated separately before a sacred landscape is reconstructed

The first stream is textual: Vedic, Upaniṣadic, Buddhist, Jain, epic and later devotional traditions name regions, rivers, cities, groves, ponds and hills. The second is archaeological and epigraphic: settlement phases, stupas, pillars, temples, sculptures, inscriptions, tanks and monasteries can establish material activity at particular times. The third is ritual practice, which includes bathing, circumambulation, offering, relic veneration, image service, monastic residence and seasonal gathering. The fourth is later pilgrimage memory, preserved in routes, temple traditions, local chronicles, oral accounts and the rebuilding of sacred sites. Each stream answers different questions. A canonical story does not date a surviving wall; a medieval inscription does not prove that the same cult existed there a millennium earlier; a modern pilgrimage centre can be historically important without being archaeologically identical with an ancient capital. Controlled comparison is therefore the governing rule.

Sacred geography: evidence streams

Figure 88 — Sacred geography must be reconstructed from separately dated textual, archaeological-epigraphic, ritual and later pilgrimage evidence before synthesis.

23.3 The Indian category of tīrtha links crossing, place and social movement

The Sanskrit word tīrtha originally carries the sense of a ford or crossing and developed a powerful religious range: a place where ordinary and sacred worlds could be crossed, a destination of pilgrimage, or a site made efficacious through divine, ascetic or ancestral association. Diana Eck has shown how Indian sacred geography is produced by networks of places rather than by one central sanctuary. For this region, the concept is especially useful because rivers, crossings and travel routes recur repeatedly in political, commercial and religious history. Yet the term should not be applied mechanically to every ancient site. Buddhist and Jain landscapes had their own vocabularies and institutions, while many local sacred places were organised around ponds, groves, hills or shrines. The wider historical point is that movement made place meaningful: repetition turned routes and destinations into socially durable maps.

23.4 Rivers created both sacred corridors and unstable historical evidence

The Ganga, Gandak, Kosi and numerous tributaries shaped settlement and mobility, but river sanctity cannot be inferred simply from hydrology. Rivers move, channels avulse, banks erode and ferry points shift. A textual river name may preserve a long cultural memory while the physical channel associated with it changes. Sacred geography must therefore combine philology with geomorphology and historical settlement evidence. At the social level, rivers could be routes for mendicants, pilgrims, merchants and rulers; boundaries between political or cultural zones; sources of water for ritual and daily life; and hazards requiring boats, embankments or seasonal adaptation. Because sacred routes depended on transport and access, a river's religious meaning was also tied to practical infrastructure. The same river could connect a pilgrimage network in one season and obstruct it in another.

23.5 The Ganga formed the southern horizon of Mithila and a major east–west religious corridor

Across many historical descriptions, the Ganga marks the southern edge of Mithila while also linking the region to Magadha, Aṅga and Bengal. This dual role—boundary and corridor—is more useful than

imagining a fixed frontier line. Ferries and riverbank settlements created points where travellers crossed between north Bihar and the southern Gangetic world. Buddhist monastic movement, Jain itinerancy, Brahmanical pilgrimage and later temple networks all benefited from this longitudinal artery. Riverbank sanctity, however, intensified at different places and periods. The Ganga's pan-Indian religious prestige cannot by itself date local ghats or prove the antiquity of a modern bathing site. What can be said securely is that the river provided a durable spatial framework within which sacred routes, economic exchange and political communication repeatedly converged.

23.6 The Sadānīrā/Gandak memory shows how a river could become a cultural boundary in narrative

The Śatapatha Brāhmaṇa's account of Videgha Māthava crossing the Sadānīrā has long been read as a memory of eastward Vedic expansion and the formation of Videha. The narrative transforms a river into a threshold between differently imagined cultural spaces. It is valuable evidence for how later Vedic tradition conceptualised region-making, but it should not be treated as a cartographic survey or a dated migration report. Identification of the Sadānīrā with the Gandak is widely accepted but does not make every detail of the narrative literal geography. Sacred geography here operates through remembered crossing: a political and ritual world is described as moving across water into a new landscape. The river is therefore both physical and conceptual, and its historical importance lies partly in that capacity to organise memory.

23.7 The Kosi warns against assuming that sacred landscapes remain physically fixed

The Kosi system has repeatedly shifted channels across the north Bihar plain. That history matters for sacred geography because villages, routes, ponds, mounds and shrines can be abandoned, relocated or reidentified after environmental change. A place-name may survive while its relation to a river changes; a temple may be rebuilt on safer ground; an image recovered from a field or channel can enter a new ritual setting. Such processes make continuity difficult to prove but historically interesting. They show that sacred geography is resilient precisely because it can be reconstructed. The problem is methodological: present proximity to a river cannot be used to establish ancient proximity, and an old narrative cannot be geolocated solely from a modern channel. Environmental history therefore protects religious history from false precision.

23.8 Groves were social spaces where mobility could become repeated sacred association

Early Buddhist texts repeatedly place teaching in groves, parks and wooded spaces near cities. Vaiśālī's Mahāvana and Ambapālī's grove are important examples. Such places were neither wilderness nor ordinary urban streets. They offered shade, room for assembly and a degree of separation from dense habitation while remaining close enough to households for food, visitors and patronage. Their sacredness emerged through repeated occupation, teaching, donation and memory rather than from monumental architecture alone. This is important because the earliest religious landscapes may leave weak archaeological signatures. A donated grove can become institutionally significant before brick monasteries appear. The social history of sacred geography must therefore include semi-open landscapes—orchards, groves and parks—that connected renunciant communities to towns without being fully urban or fully rural.

23.9 Ponds and tanks joined ritual efficacy to water management

Ponds are among the most persistent features of sacred landscapes in Mithila and eastern India. They can support bathing, domestic water, irrigation, animals and ritual while also serving as named landmarks around temples or settlements. Their chronological interpretation requires caution because ponds are repeatedly desilted, enlarged, renamed and rebuilt. Yet inscriptions and archaeology sometimes allow firmer dating. The seventh-century Mandar Hill record associated with Queen Koṇadevī is especially valuable because it explicitly commemorates the making of a puṣkariṇī, demonstrating royal female patronage of sacred-water infrastructure. Such evidence shows why water works belong to social as well as religious history: constructing a tank could enhance ritual prestige while providing a durable public resource. Sacred and practical functions were not opposites.

23.10 Campā's Gaggārā lotus pond is a strong example of a named water-place in textual sacred geography

Buddhist Vinaya and discourse traditions repeatedly locate the Buddha at Campā on the bank of the Gaggārā lotus pond. The references establish the pond as a remembered setting for teaching, monastic procedure and interaction with lay followers. They do not prove the exact archaeological location of the pond or the date of any surviving water feature at modern Champā/Nathnagar. Even so, the recurrence is historically important. It shows that urban sacred geography could crystallise around a water landmark rather than only around a monastery or shrine. Campā's wider archaeology—fortification, habitation, craft activity, coins and drainage—places this remembered religious setting inside a substantial urban economy. The sacred pond was therefore imagined within a city of households, markets and movement, not in isolation from ordinary life.

How a place becomes a sacred centre

Figure 89 — A sacred centre can emerge through repeated association, materialisation, route formation and renewal; the sequence is cumulative rather than mechanically linear.

23.11 Vaiśālī became sacred through the accumulation of several religious maps rather than one exclusive tradition

Vaiśālī is unusually rich because Buddhist, Jain and later Brahmanical memories overlap with major archaeological remains. Buddhist texts place the Buddha in and around Vesālī, at groves and shrines; Jain

tradition gives the wider Vaiśālī–Videha landscape a central place in the life and itinerancy of Mahāvīra; archaeological work has identified urban remains, a relic stupa, the Aśokan pillar at Kolhua and later monastic structures. These elements do not belong to one moment. Their accumulation is itself the history. A city remembered by several communities could attract repeated investment because earlier prestige made later monumentality meaningful. Poly-religious sacred geography is therefore not a contradiction: different groups could claim, reinterpret and revisit the same regional node while maintaining distinct doctrines and institutions.

23.12 Relic stupas and pillars turned memory into durable spatial markers

The Buddhist relic tradition gives physical place unusual importance because bodily remains and commemorative stupas create fixed centres within a religion also characterised by monastic mobility. At Vaiśālī, the excavated relic stupa and the Mauryan pillar landscape demonstrate the long materialisation of Buddhist memory. The exact relationship between an excavated monument and a canonical event must still be argued, not assumed. Aśokan pillars in particular belong to a third-century BCE imperial programme; they cannot be treated as structures from the Buddha's lifetime. Their significance lies in the later fixing and monumentalising of places already meaningful within Buddhist memory. Once marked, such sites could support pilgrimage, patronage, maintenance and new narratives, producing a feedback loop between memory and material form.

23.13 Jain sacred geography relied heavily on movement, seasonal residence and remembered biography

Jain traditions associated Mahāvīra with Vaiśālī, Videha, Mithilā and Campā, while monastic discipline made routes, rainy-season residence and household support central to religious life. This produces a different spatial logic from a landscape dominated by fixed temples. Repeated residence can sacralise a city or village even when early material remains are difficult to identify. Later Jain pilgrimage then monumentalised selected biographical associations. The historian must distinguish these stages. A modern or medieval shrine at a remembered birthplace or residence is strong evidence for later devotion but not automatically for the precise location of an early event. The continuity that can often be reconstructed most confidently is regional rather than architectural: communities repeatedly returned to the same named zones and made them part of Jain historical identity.

23.14 Mithilā's sacred prestige began in more than one textual tradition

Mithilā and Videha are important in late Vedic and Upaniṣadic literature as settings of royal ritual, philosophical debate and the figure of Janaka. Epic and later devotional traditions add the Sita–Janaka–Rama cycle, creating another powerful map of sacred memory. These traditions need not be collapsed into one chronology to explain their cumulative effect. A region already prestigious as the land of Janaka could later be reinterpreted through Ramayana devotion, while philosophical memory and pilgrimage memory continued side by side. This layering helps explain why the name Mithila carried cultural authority beyond any single archaeological capital. Sacred geography can be attached to a region, courtly memory or narrative landscape even when the exact location of a palace, sacrificial field or episode remains uncertain.

23.15 Janakpur demonstrates the historical re-creation of a sacred city

Richard Burghart's classic study of Janakpur is methodologically important because it separates sacred claims about an ancient city from the historical processes through which Janakpur emerged and re-emerged

as a pilgrimage centre. Ascetics, priests, rulers, landholders and pilgrims participated in identifying and materialising places connected with Janaka and Sita. The present monumental landscape is therefore evidence of powerful historical devotion, not a transparent survival of Bronze or Iron Age urban fabric. This does not diminish Janakpur's significance; it clarifies it. Sacred cities can be rebuilt through memory, land grants, temple patronage, markets and pilgrimage. Their authenticity for devotees operates through a different logic from archaeological identity. A social history must examine both without forcing one to validate the other.

23.16 Ramayana localisation connected Mithila to a transregional narrative world

The Ramayana allowed local places in Mithila to participate in a story known across South and Southeast Asia. Janaka's court, Sita's birth or discovery, the bow, the marriage and related episodes could be localised in particular fields, ponds, shrines and routes. Localisation is historically productive because it attracts patrons and pilgrims while giving communities a place within a larger sacred narrative. Yet every localisation has its own documentary history. Some identifications are old, others become visible only in relatively recent sources. Rather than asking whether all modern sites are literally the exact locations of epic events, historians can ask when an identification appears, who sustains it, how it changes land use and movement, and how it interacts with other religious landscapes. This converts a potentially irresolvable authenticity dispute into a researchable social history.

23.17 Janakpur's ponds and parikrama show how a sacred city is organised through movement

The later pilgrimage landscape of Janakpur is structured not only by temples but by ponds, processional paths and circuits of circumambulation. Sacred water, stopping places and movement among shrines turn the city into a ritual sequence rather than a collection of isolated monuments. Such circuits also create economic rhythms: pilgrims require food, lodging, transport, ritual services and market goods, while institutions maintain buildings and water bodies. The antiquity of each pond or stopping place must be established separately, and present ritual prominence should not be equated with ancient date. Still, the spatial form itself is historically revealing. Parikrama converts geography into repeated embodied practice. Through walking, bathing and narration, participants continually reproduce a regional sacred map.

23.18 Mandar Hill is one of Aṅga's clearest examples of a natural feature becoming a multi-layered sacred centre

Mandar rises conspicuously from the landscape south of Bhagalpur and has accumulated Vaiṣṇava, Jain and later local religious associations. Its physical prominence helps explain why it could become a durable landmark, but topography alone did not make it sacred. The strongest historical anchor is epigraphic: the Later Gupta-period inscriptions associated with Ādityasena's family connect the hill with Narahari/Narasimha devotion and with a commemorated tank. Later narratives and pilgrimage practices added further meanings. Mandar should therefore be treated as a site biography. Different communities did not necessarily use the hill in the same way or at the same time, and later mythic identifications cannot be projected automatically into the seventh century. The value of Mandar lies precisely in the possibility of separating its layers.

23.19 The Mandar tank inscription demonstrates how patronage could bind deity, water and royal memory

The Mandar Hill inscription recording Queen Koṇadevī's construction of a puṣkariṇī is unusually concrete evidence for the social production of sacred space. A tank at the foot of a sacred hill can serve pilgrims, local residents, ritual bathing and the practical water needs of an institution or settlement. The inscription turns that work into public memory by attaching it to royal status and piety. Gender matters here because a queen appears as a named patron rather than as an anonymous participant. The case warns against defining religious patronage only as temple construction. Water management, approach routes, rest facilities and landscape modification can be equally important in making a sacred centre durable. Monumentality often depends on infrastructure that is less visually dramatic but more socially pervasive.

23.20 Mandar's later plurality illustrates how sacred places can be shared without becoming religiously identical

Mandar is claimed within multiple religious narratives. Such plurality should not be forced into a simple sequence in which one religion replaces another. Sacred hills can sustain parallel claims because different groups emphasise different episodes, deities, ascetics or ritual zones. Shared geography does not imply shared theology. At the same time, practical resources—paths, water, markets, lodging and access—can be used by diverse visitors. Early medieval Bihar and Bengal more generally show overlapping Buddhist, Brahmanical and Jain religious centres, as Birendra Nath Prasad's archaeological synthesis emphasises. Mandar offers a regional instance of this wider pattern. The historian should therefore map institutions and practices, not colour an entire hill permanently with one sectarian label.

Selected regional sacred anchors

Figure 90 — Selected regional anchors illustrate different kinds of sacred evidence in Mithila–Videha, Vajji–Vaiśālī and Aṅga; their dates and evidentiary strengths are not uniform.

23.21 Vikramaśīla transformed the Aṅga–Bhagalpur Ganga corridor into a major monastic-intellectual sacred node

The excavated remains at Antichak, generally identified with Vikramaśīla, represent a large Pāla-period Buddhist monastic complex in the Bhagalpur region. Its importance belongs to a later chronology than early

Campā, but it demonstrates continuity in the regional value of the Ganga corridor for movement and institutional concentration. A mahāvihāra required land, food, construction materials, teachers, students, ritual spaces and connections to patrons. It was therefore simultaneously an intellectual, religious and economic landscape. Pilgrims and scholars could approach a monumental complex whose spatial order itself communicated institutional authority. Vikramaśīla should not be projected backward into ancient Aṅga, but its later presence shows how the region continued to generate sacred centres through new forms of monastic organisation.

23.22 Pilgrimage routes were social corridors, not lines drawn independently of roads and seasons

Sacred journeys depended on the same material conditions as other travel. Rivers required ferries; monsoon conditions altered roads; forests and political insecurity affected route choice; towns offered food and lodging. A pilgrimage circuit therefore grew where memory and mobility could reinforce one another. Religious centres near commercial routes could benefit from existing traffic, while popular shrines could themselves increase demand for transport and markets. The relationship should not be reduced to the claim that “trade caused pilgrimage” or the reverse. More often, several forms of mobility shared corridors and facilities. This is particularly plausible along the Ganga and in the urban networks linking Vaiśālī, Mithilā, Campā and later Bhagalpur-area institutions. Sacred geography was embedded in transportation geography.

23.23 Pilgrimage created recurring demand for hospitality, food and ritual services

A sacred centre becomes socially consequential when visitors arrive repeatedly. Pilgrims need grain, cooked food, water, fuel, shelter, boats, carts, guides, offerings and sometimes medical assistance. Priests, monks, ascetics and temple servants also require maintenance. Markets near sacred places can therefore respond to religious calendars without becoming purely “religious economies.” Local households may host visitors or sell provisions; artisans may produce lamps, vessels, textiles, images and architectural components; rulers or donors may finance wells and rest facilities. The scale varies enormously and must be demonstrated rather than assumed. Still, the principle is important: sacred geography redistributes demand in space and time. It can make an otherwise modest settlement seasonally significant or sustain specialised services around a major institution.

23.24 Artisans helped convert remembered places into visible sacred landscapes

Stupas, pillars, temples, icons, railings, seals, manuscripts and ritual vessels all require skilled labour. A sacred narrative becomes materially durable only when patrons can mobilise stoneworkers, brickmakers, metalworkers, painters, carpenters and other specialists. The Pāla-Sena sculptural corpus of Bihar and Mithila demonstrates sophisticated regional workshops, while monastic sites required large-scale brick construction. Artisans were not merely executing abstract theology. They translated iconographic and architectural requirements into local materials and styles. Their mobility could also connect sacred centres, spreading technical conventions across regions. Sacred geography was therefore partly a geography of labour. The concentration of religious institutions created demand for skills, while established craft zones made certain kinds of monumentality possible.

23.25 Women appear in sacred geography as patrons, renouncers, pilgrims and remembered figures

Sacred landscapes were not produced by male rulers and priests alone. Ambapālī's grove donation at Vaiśālī is central to Buddhist memory; Jain traditions preserve women's participation in renunciation and lay support; Queen Koṇadevī's Mandar tank inscription gives epigraphic evidence for female royal patronage; Sita/Janaki becomes the defining sacred figure of later Janakpur. These forms of presence are not equivalent. A goddess or epic heroine does not automatically reveal ordinary women's property rights, and hagiographic narratives require source criticism. Nevertheless, the landscape records multiple forms of female agency and representation. Women could finance infrastructure, enter religious communities, support mendicants, participate in pilgrimage and become the focus of regional devotion. Gender is therefore built into the making of sacred place.

23.26 Rulers used sacred landscapes to make authority visible, but religious patronage was not simple propaganda

Pillars, tanks, temples, monasteries and grants could associate rulers with piety, generosity and regional order. Aśokan monumentality at Buddhist sites and Later Gupta patronage at Mandar demonstrate different ways in which political power entered sacred space. Pāla support for great monasteries offers another. Yet rulers patronised institutions for multiple reasons, and individual religious preference cannot be read mechanically from every donation. Sacred patronage could stabilise routes, provide water, cultivate alliances with specialists, enhance dynastic memory or support learning. Communities also had agency: monks, priests and local elites could attract and redirect patronage. Sacred geography was thus produced through negotiation between political resources and institutional interests rather than imposed unilaterally from a court.

23.27 Sacred geography contributed to regional identity without creating immutable cultural borders

Mithila, Vajji and Aṅga each accumulated distinctive sacred associations: Janaka and Sita in Mithila, the Buddha and Mahāvīra at Vaiśālī, Campā's renunciant memories, Mandar's hill traditions and later Vikramaśīla in the Bhagalpur region. These associations could strengthen regional identity because places gave large narratives local coordinates. Yet sacred maps overlapped political borders and changed with dynasties, migrations and routes. Pilgrims routinely crossed regions; texts linked local sites to pan-Indian cosmologies; monasteries recruited beyond their immediate hinterlands. Sacred geography should therefore be understood as a network of centres and corridors, not a wall around a culture. Regional identity emerged from repeated association without requiring isolation.

23.28 Poly-religious landscapes are better understood through shared infrastructure and differentiated meaning

A pond, road, market or hill can serve multiple communities while remaining ritually distinct for each. Vaiśālī, Campā and Mandar all demonstrate forms of layered religious memory. Early medieval Bihar and Bengal provide particularly strong archaeological evidence for Buddhist, Brahmanical and Jain centres in overlapping spatial fields. Competition for patrons was possible, but coexistence and borrowing were also normal. Shared infrastructure should not be mistaken for doctrinal synthesis; different communities could use the same route or town while preserving separate institutions. Conversely, sectarian labels should not

obscure the ordinary services that made religious life possible. A historically adequate map therefore needs two layers at once: differentiated sacred meanings and common material environments.

Sacred landscape and local economy

Figure 91 — Sacred centres could concentrate recurring demand for hospitality, household support, specialist labour and transport while remaining embedded in wider local economies.

23.29 Evidence is strongest for named associations and material investment, weaker for exact ancient localisation and uninterrupted continuity

Several conclusions are robust. Texts repeatedly associate particular regional nodes with religious teachers and narratives; archaeology demonstrates major urban and religious investment at Vaiśālī and later Vikramaśīla; Campā's Gaggara pond is a stable element of Buddhist textual memory; Mandar preserves unusually strong epigraphic evidence for royal sacred-water and Vaiṣṇava patronage; later Janakpur became a major materialised landscape of Janaka–Sita devotion. The weakest claims are those that identify a modern shrine, pond or field as the exact location of an undated ancient event solely because local tradition says so. The appropriate response is neither credulity nor dismissal. Later identifications are themselves historical evidence and should be dated, mapped and related to landholding, patronage, pilgrimage and community memory.

23.30 Conclusion: sacred geography was a cumulative social technology of memory, movement and materialisation

Across Mithila, Vajji and Āṅga, sacred geography emerged when narratives and institutions became attached to specific rivers, groves, ponds, hills, cities and routes. Some associations are preserved in early texts; others become visible through inscriptions, archaeology or much later pilgrimage. Their dates differ, but the processes recur. Repeated visitation creates memory; patronage creates durable markers; water and roads make access possible; ritual specialists organise practice; markets and households support visitors; rebuilding renews claims after environmental or political change. Sacred places are therefore neither timeless survivals nor arbitrary inventions. They are cumulative social formations. The next chapter turns from these spatial structures to their temporal counterpart: festivals and calendrical culture, through which communities repeatedly activated sacred places at particular times of year.

Table 23.1 — Evidence for sacred geography, and limits of inference

Evidence / place	What it supports	What it does not prove alone	Source control
Videha / Mithilā in Vedic–Upaniṣadic texts	Regional and courtly sacred-intellectual memory	Exact archaeological location of every narrated event	Textual geography; date individual texts and layers
Vaiśālī: relic stupa, Aśokan pillar, monastic remains	Long-term Buddhist materialisation in an already important city	That all remains belong to the Buddha's lifetime	Archaeological and Mauryan/ later monumental layers must be separated
Vaiśālī–Videha Jain traditions	Repeated regional association with Mahāvīra and Jain itinerancy	Exact location/date of every later shrine	Canonical memory plus later pilgrimage history
Campā and Gaggārā lotus pond	Stable Buddhist textual association of a named urban water-place	Exact archaeological identification of the pond	Textual anchor combined cautiously with Campā archaeology
Mandar Hill inscriptions	7th-century royal Vaiṣṇava association and Queen Koṇadevī's tank patronage	Exclusive sectarian control or antiquity of all later myths	Strong epigraphic anchor for one historical layer
Vikramaśīla / Antichak	Large Pāla-period Buddhist monastic landscape in Aṅga–Bhagalpur corridor	Continuity with ancient Campā institutions	Excavated early-medieval institutional anchor
Janakpur pilgrimage landscape	Historically powerful Janaka–Sita localisation, ponds, temples and circuits	Archaeological identity with ancient Mithilā simply from tradition	Study reconstitution, patronage and pilgrimage as historical processes
Sacred rivers, ponds and routes	Material settings for bathing, movement, hospitality and ritual	Automatic sacredness or unchanged ancient channels	Combine environmental history with dated religious evidence

Chapter 24 — Festivals and calendrical culture

Chapter argument. Calendrical culture in Mithila, Vajji and Aṅga developed through the interaction of lunar and solar reckoning, seasonal ecology, monastic discipline, specialist astronomy, household ritual and regional festival practice. The chapter distinguishes durable calendrical structures from the much more difficult question of the antiquity of individual festivals, and treats the ritual year as a social technology that coordinates labour, gendered practice, markets, sacred places and institutional authority.

24.1 Calendars are social infrastructure, not merely systems for naming dates

A calendar coordinates people who otherwise live by different rhythms. Farmers watch rain, soil and crop cycles; ritual specialists calculate lunar days and auspicious combinations; monasteries organise communal observances; households schedule fasts, marriages and ancestor rites; rulers and scribes date grants, taxes and public acts. Festivals gather several of these clocks into a shared moment. The history of calendrical culture in Mithila, Vajji and Aṅga must therefore be written as a history of coordination. It is not enough to list holidays. The important questions are how dates were calculated, who possessed calendrical expertise, which activities were permitted or avoided, how seasonal ecology shaped observance, and how different communities could inhabit the same year differently. A ritual year is a social arrangement superimposed on astronomical and environmental cycles, and that arrangement changes over time.

24.2 Four evidence streams must be kept separate before the ritual year is reconstructed

Calendrical history draws on evidence that differs greatly in date and purpose. Astral and ritual texts define categories such as tithi, pakṣa, month, season and nakṣatra, but they do not automatically describe village practice in Mithila. Buddhist and Jain disciplinary texts preserve lunar observances and rainy-season residence, yet their normative rules require distinction from local behaviour. Inscriptions and dated manuscripts reveal eras, regnal years and the practical use of calculated dates. Pañcāṅgas and almanacs show specialist calendrical knowledge in later periods. Finally, ethnography and oral traditions document annual rites, women's observances, household routines and local festival sequences. Hiroshi Ishii's comparison of Mithila and Nepal is particularly valuable for the recent ritual year, but it cannot by itself prove ancient origins. Historical synthesis begins only after each layer is dated.

Calendrical culture: evidence streams

Figure 92 — Calendrical history must separate astral-textual, monastic, epigraphic-almanac and ethnographic evidence before reconstructing a ritual year.

24.3 Early Vedic ritual already required coordination of lunar, solar and seasonal time

Vedic ritual was inseparable from timing. New- and full-moon sacrifices, seasonal rites and soma ceremonies depended on recurring astronomical intervals. The ritual calendar therefore transformed celestial observation into collective scheduling. The relevant point for eastern India is not that a complete later Hindu calendar existed from the beginning, but that the expansion of Vedic ritual culture into Videha carried techniques for distinguishing lunar phases, seasons and appropriate ritual moments. The Śatapatha Brāhmaṇa's Videha materials belong to a world in which ritual authority and temporal knowledge were closely connected. Because textual redaction is complex, individual prescriptions cannot simply be mapped onto a specific settlement or century in Mithila. Yet the broader institutional principle is secure: ritual specialists gained authority partly by knowing when an action should occur.

24.4 The lunar fortnight made recurring observance easy to organise across mobile communities

The waxing and waning halves of the lunar month provided a visible and repeatable framework. Full moon and new moon were not arbitrary dates; they could be observed without a written almanac, even if exact ritual reckoning became increasingly technical. The division of the month into tithis allowed more precise placement of rites such as eighths, elevenths, fourteenths and fifteenths. This framework survived across traditions because it was portable. A court, village, monastery or travelling ascetic community could share the same basic lunar sequence while attaching different meanings to particular days. Later Mithila ritual life, as Ishii observed, remained heavily dependent on lunar dates. Continuity of calendrical form, however, does not prove continuity of every festival attached to it; the container can be old while the ritual content changes.

24.5 Lunisolar coordination required correction because lunar months do not equal the solar year

Twelve synodic lunar months fall short of the solar year. A ritual system tied both to lunar phases and to seasons must therefore correct the difference. Indian calendrical traditions developed intercalation so that months and seasonal expectations did not drift indefinitely apart. This is socially important because the same named month had to remain broadly associated with monsoon, harvest or winter conditions if agricultural and ritual cycles were to remain intelligible. Intercalation is evidence of institutional timekeeping: someone had to know when adjustment was required, and communities had to accept the result. It also warns historians against translating traditional dates into modern calendar dates without calculation. The same festival can shift across the Gregorian calendar even while remaining fixed to its lunar rule.

24.6 The Vedāṅga Jyotiṣa represents a major stage in the formalisation of ritual astronomy, but its date is debated

The Vedāṅga Jyotiṣa describes a five-year cycle, lunar months, tithis, nakṣatras, solstitial points and procedures for coordinating ritual time. Its importance lies in making calendrical computation explicit. Scholars have long debated its chronological layers and the astronomical observations behind them, so it should not be assigned casually to a single date and then used as a direct record of Videha. What can be said with confidence is that ritual timing stimulated mathematical and observational astronomy in early India. Later calendrical specialists inherited a conceptual world in which astronomy served social decisions: when to sacrifice, travel, marry, fast, begin a rite or recognise an intercalary month. This relationship between calculation and practice eventually became central to regional pañcāṅga culture.

A lunisolar ritual calendar coordinates several clocks

Figure 93 — A lunisolar ritual calendar coordinates lunar phases, solar position, astral reckoning and seasonal-local conditions; intercalation prevents unlimited drift between lunar months and the solar year.

24.7 Seasons were not merely astronomical divisions; they were experienced through monsoon ecology

A seasonal calendar in the middle and eastern Ganga plains had to confront rainfall, flooding, heat, insects, crop labour and road conditions. Ishii's Mithila research is especially useful because it resists a

simplistic idea that the whole monsoon ritual period was either uniformly inauspicious or uniformly dominated by agricultural work. He found that the rainy months contained many annual rites and that their timing intersected with, but did not simply mirror, rice cultivation. The monsoon also heightened danger from snakes and water-related conditions, helping explain why protective rites could cluster seasonally. Calendrical culture thus converts ecological recurrence into symbolic and social form. The relationship is probabilistic, not deterministic: the existence of snakes in the rains does not prove the origin of every serpent rite.

24.8 Buddhist uposatha institutionalised lunar observance as a recurring communal discipline

Buddhist monastic regulation adapted existing Indian lunar observance days. The uposatha became a regular occasion for communal assembly and recitation of the monastic code, especially at the end of the lunar fortnight. The Vinaya tradition even preserves concern that monks should know how to calculate the fortnight correctly. This is important for the history of Vajji and Aṅga because monastic communities at places such as Vaiśālī and Campā did not live outside ordinary time; they participated in a widely intelligible lunar framework while giving it institutional Buddhist form. The calendar created regular accountability. It also connected dispersed monasteries through a shared rhythm without requiring a central bureaucracy to announce every date.

24.9 The rains residence converted climate into an institutional season

The Buddhist vassa or rains residence restricted ordinary monastic wandering during the monsoon and thereby altered relations between monks, donors and settlements. Residence concentrated teaching, maintenance and provisioning in particular places for a defined season. The end of the rains was marked by further communal procedures. This is calendrical culture in a strong institutional sense: ecological conditions, disciplinary rules and social support were synchronised. In regions crossed by swelling rivers and muddy roads, seasonal residence also had practical consequences. Yet the rule should not be reduced to environmental convenience; it carried ethical and communal meanings within the Vinaya. Nor should later festivals attached to the end of rains be projected wholesale into the earliest period. The historical core is the structuring of monastic mobility by season and lunar reckoning.

24.10 Jain rainy-season discipline created a parallel but distinct temporal institution

Jain canonical and disciplinary traditions also organised mendicant movement around the rains. The Kalpa Sūtra and related rules associate Paryuṣaṇā with the monsoon residence and specify temporal limits for settling into the rainy-season stay. Such prescriptions are particularly relevant to the Vaiśālī–Videha landscape because Jain memory repeatedly places Mahāvīra and his community in this wider region. The annual rhythm connected ascetic restraint to lay support: monks and nuns stayed within a limited area, householders provided alms, and teaching became locally concentrated. Buddhist and Jain rains institutions should not be collapsed into one tradition. Their doctrinal meanings and rule systems differed, even though both demonstrate how South Asian renunciant movements turned monsoon seasonality into predictable religious time.

24.11 Calendrical regularity allowed institutions to plan labour, food and hospitality

A festival or observance changes work before the sacred date arrives. Grain must be stored or purchased, lamps and vessels prepared, houses or compounds cleaned, offerings assembled, guests accommodated and ritual specialists engaged. Monastic lunar observances similarly require assembly, recitation and often intensified lay participation. Once dates become predictable, households and markets can anticipate demand. This is one reason calendars are economic instruments as well as religious systems. The effect is not necessarily large enough to create a separate “festival economy” in every settlement, but repeated annual demand can sustain particular crafts, foods and services. Historical analysis should therefore examine preparation time as well as festival day itself.

24.12 Dated inscriptions reveal another calendrical world: the time of rulers, donations and legal memory

Inscriptions commonly locate acts within regnal years, eras, months, lunar fortnights and tithis. Such dating transforms a donation or construction into an event that can be remembered and legally cited. The calendar here is not primarily festive; it is administrative and commemorative. Yet the same calendrical vocabulary links political acts to ritual time, especially when a grant or dedication is made on an auspicious day. In eastern India, changing dynasties introduced or used different eras while local religious calendars continued to operate. Historians must therefore distinguish the epoch used to number years from the system used to identify months and days. A single inscription may combine both. This complexity later becomes highly visible in manuscript colophons and regional almanacs.

24.13 The Lakṣmaṇa Sena era shows that regional year-counting could coexist with wider Indian systems

In later Mithila and Tirhut, the Lakṣmaṇa Sena era became one element of chronological practice. Nineteenth-century calendrical scholarship already noted its use in Tirhut and Mithila alongside Vikrama or Śaka reckoning and also recorded disagreement over its exact epoch. The important historical lesson is not to impose one modern conversion formula on every document without source criticism. Eras are social conventions transmitted by scribes, pandits and almanac makers, and their use can vary by locality and document type. Regional year-counting did not replace the lunar architecture of months, fortnights and tithis. Instead, several chronological layers could coexist: one system named the year, another placed the ritual day, while local custom determined how that date was observed.

24.14 Pañcāṅga specialists mediated between astronomical computation and household decisions

The later pañcāṅga condenses complex astral calculations into a usable annual almanac. The familiar five limbs—tithi, weekday, nakṣatra, yoga and karaṇa—allow specialists to evaluate dates more precisely than simple lunar observation would permit. Judy Pugh’s study of North Indian almanac culture shows that auspiciousness is task-specific: a period avoided for one life-cycle rite may remain perfectly usable for farming, trade or house construction. This is crucial for Mithila. The pañcāṅga should not be imagined as a rigid schedule mechanically controlling everyone. It is a decision technology interpreted by specialists and households. Different families may consult different authorities, and urgent practical work can follow season and necessity even when ritual choices await an auspicious moment.

24.15 Muhūrta culture distributed expertise unevenly across society

Knowing that a marriage, journey or initiation requires an auspicious time is different from being able to calculate that time. Calendrical complexity therefore creates specialist roles. Brahmanical ritual experts, astrologers and learned householders could gain authority through access to texts, calculation and inherited practice. At the same time, everyday calendrical knowledge was widely distributed: people knew major lunar days, seasonal thresholds and festival sequences without performing full astronomical calculation. The social history of time is thus also a history of expertise. Calendrical specialists did not monopolise time itself; they mediated difficult decisions within a temporal language shared by the wider community. This distinction prevents the assumption that every observed festival required elite textual direction.

24.16 Life-cycle rites occupied a different temporal logic from annual festivals

Annual festivals recur because the calendar reaches a specified point. Life-cycle rites depend first on a birth, marriage, death or other event and only then on calendrical selection. The two systems interact when a marriage season is preferred or a particular interval is avoided. Ishii's comparison notes that marriage and coming-of-age rites cluster differently from many monsoon observances, and Pugh similarly emphasises that auspiciousness depends on the task. This matters historically because a dense festival season does not imply that all ritual activity peaked at the same time. Household calendars contain several overlapping sequences: annual festivals, periodic vratas, ancestor observances and event-driven rites. Chapter 25 examines life-cycle and mortuary rituals directly; here the point is that calendrical culture coordinates them without making them identical.

24.17 Women's vratas demonstrate that calendrical culture also organised gendered religious agency

Ethnographic studies of Mithila repeatedly show women observing a large number of vratas linked to particular weekdays, tithis, months and family aims. Ishii found this pattern especially prominent in Mithila. Such observances could involve fasting, storytelling, drawing, bathing, offerings and restrictions on food or movement. They should not be romanticised as automatically empowering, because many articulate ideals of marriage, fertility and family duty. Yet they gave women specialised ritual knowledge, recurring gatherings and forms of religious authorship within domestic and neighbourhood space. Calendrical history must therefore include who remembers dates, prepares ritual materials, teaches songs and stories, and performs the bodily discipline of fasting. The household ritual year is partly built through women's labour.

24.18 Sāmā-Cakevā provides unusually rich ethnographic evidence for a women-centred Maithil festival cycle

Coralynn Davis's long-term research offers one of the best documented examples of a distinctly Maithil annual festival. Sāmā-Cakevā is performed by girls and women during Kārttika and culminates around the full moon. Clay or other figurines, songs, narrative play, brother-sister relations and movement to ponds, rivers or fields are central to the observance. Davis shows that the festival is not merely a fossilised myth: performers interpret gender, family authority and relational obligations through it. Its calendrical placement helps structure a sequence of repeated evening gatherings. Historically, however, the existence of a Purāṇic or Kṛṣṇa-related narrative should not be used to claim an undemonstrated ancient date for the festival in its present form. Ethnography securely documents modern and recent practice; earlier history requires separate evidence.

24.19 Madhushrāvaṇī connects monsoon time, marriage and women’s narrative-ritual practice

Madhushrāvaṇī is another major Maithil example of the way a festival cycle can organise domestic time. Ethnographic descriptions place it in the monsoon month of Śrāvaṇa and associate it especially with newly married women, goddess worship, stories, household art and conjugal well-being. The observance reveals several layers at once: a lunar date, a seasonal setting, marital status, women’s ritual knowledge and the material preparation of aripan and offerings. Its importance to social history lies less in proving remote antiquity than in showing how the calendar classifies participants. Not everyone performs the same rite simply because they share a region. Gender, marriage stage, caste, household tradition and locality determine who participates and how.

24.20 Chhath demonstrates the power of a solar-facing rite embedded within a lunar festival calendar

Chhath is today among the most publicly visible festivals of Bihar and the adjoining Nepal plains. Its central offerings to the setting and rising sun are made at water bodies, while the date is fixed through the lunar month of Kārttika. This combination is a useful reminder that “solar” and “lunar” are not mutually exclusive ritual systems: a lunar calendar can schedule a rite directed to the sun. Modern practice involves fasting, ritual purity, baskets of offerings, household cooperation and large gatherings at ghats. Historical caution is essential. Ancient Indian sun worship is well documented, but that does not establish an unbroken direct line to the present Chhath complex. Ethnographic scholarship explicitly warns against treating the modern regional festival as simply identical with ancient solar cult.

24.21 Moon-oriented and regional rites show that the same celestial body can support highly local meanings

Mithila’s ritual year also contains observances focused on the moon, including regional forms such as Chaurchan. Their significance lies in the localisation of a pan-Indian calendrical object. The moon determines tithi throughout much of South Asian ritual life, but particular narratives, foods, household arrangements and social meanings vary regionally. Claims that a specific modern festival was founded by a named medieval ruler require stronger evidence than later popular accounts alone. A safer historical method is to document the rite securely where evidence is available and then examine older calendrical, astronomical and narrative materials separately. Regional calendrical culture is not less historical because some origin stories remain uncertain; the development of those origin stories is itself part of cultural history.

24.22 Festival cycles often cluster at seasonal transitions rather than being evenly distributed through the year

The annual ritual calendar is not a uniform chain of equally weighted days. Ishii’s analysis of Mithila shows marked seasonal concentrations, including a dense monsoon sequence and major autumnal complexes. Durgā-related observances, Dīpāvalī or Lakṣmī rites, Chhath and Sāmā-Cakevā occupy a relatively compact portion of the post-monsoon calendar, while other rites cluster around spring or the onset of rains. Seasonal concentration allows one festival to prepare social and material conditions for another: cleaned houses, renewed utensils, market purchases, travel and kin visits can overlap. But clustering also intensifies labour, especially for those responsible for food, cleaning and ritual preparation. The calendrical year therefore redistributes workload as well as sacred attention.

One year, overlapping ritual rhythms

Figure 94 — The ritual year contains overlapping seasonal, sectarian, household and recurrent observance cycles rather than one uniform sequence followed identically by everyone.

24.23 Agricultural season and ritual season intersect, but one cannot be reduced to the other

It is tempting to explain every festival as a disguised agricultural rite. That approach is too simple for Mithila, Vajji and Aṅga. Crop cycles matter greatly: sowing, transplanting, harvest and storage affect household resources and available labour. Yet rituals can occur during agricultural slack periods, during risky monsoon conditions, or for reasons rooted in narrative and sectarian traditions rather than cultivation. Ishii specifically cautioned against treating the four-month monsoon period as identical with the busiest agricultural season. A better model is interaction. Agricultural work shapes what is practicable; ritual calendars provide independent classifications of time; households negotiate between the two. This explains why farming can proceed despite calendrical inauspiciousness that would postpone a marriage or other optional rite.

24.24 Festival time can activate sacred geography by turning ordinary routes and water places into temporary centres

The preceding chapter examined sacred geography as accumulated place. Festivals add periodic intensity to that geography. A pond, riverbank, temple courtyard, village road or market can be ordinary on most days and become a major ritual centre at a calendrically specified moment. Chhath makes this especially visible at ghats; Sāmā-Cakevā ends with movement toward water or fields; fairs and pilgrimage days similarly concentrate visitors along routes that serve everyday transport. The relationship works in both directions. Sacred places attract festivals, while repeated festivals strengthen the sacred reputation of places. Temporary structures, lighting, cleaning and crowd management can leave lasting improvements or disputes over access. Calendrical culture therefore converts space into event.

24.25 Markets respond to predictable festival demand, but ritual consumption is socially differentiated

Annual observances create recurring demand for fruit, grain, sugar, cloth, bamboo baskets, pottery, lamps, pigments, flowers and specialised foods. Artisans and traders can anticipate these cycles because the date is known in advance even when it shifts in the Gregorian calendar. Yet the economic burden of observance is uneven. Wealthier households may display generosity through larger offerings or feasts; poorer households may simplify rites, borrow, cooperate with kin or participate through labour rather than expenditure. Religious calendars can thus make inequality visible without reducing devotion to consumption. Historians should ask who paid, who produced, who cooked, who transported goods and who received gifts. Festival economy is a pattern of temporary intensification embedded in the wider household and market economy.

Festival time reorganises labour and exchange

Figure 95 — Festival dates concentrate household labour, specialist services, market demand and use of public space, but the burdens and benefits are socially unequal.

24.26 Calendrical participation varies by caste, sect, gender, age and household tradition

A regional calendar is not a list that every resident follows identically. Ishii's comparative work found that even rites occurring on the same dates could differ substantially in name and performance. Within Mithila, variation is equally important. Some observances are strongly associated with women; some with particular stages of marriage; some with Brahmanical household practice; some are broadly shared across caste communities; Buddhist and Jain institutions follow their own disciplinary cycles. Muslim communities in Mithila and Anga have also long inhabited Islamic lunar time alongside the regional agricultural and civic year. A complete social history therefore treats calendars as overlapping rather than singular. Shared chronology does not erase religious difference, and religious difference does not prevent neighbours from sharing seasonal markets, roads or public spaces.

24.27 The India–Nepal border did not divide the Maithil ritual year into two sealed systems

Mithila extends across the modern India–Nepal frontier, and ritual practice has long crossed that political line through marriage, pilgrimage, markets and kinship. Ishii's fieldwork on both sides of the border showed strong cultural continuity while also identifying differences created by state calendars and wider Nepalese traditions. Nepal's official solar calendar and local lunar ritual dates do not always coincide in the same way as Indian administrative time. This creates an important methodological point: modern national calendars can overlay rather than erase older regional schedules. Janakpur's festivals, marriage circuits and pilgrimage draw participants from both sides, making calendrical culture a transborder social institution even when governments use different official dates and holidays.

24.28 Printed almanacs changed the circulation of calendrical authority without eliminating oral expertise

Manuscript and print culture made astronomical tables and ritual dates reproducible beyond a single teacher–student chain. By the colonial period, regional and North Indian almanacs could circulate widely, allowing households and priests to compare dates and predictions. Print did not automatically standardise everything. Different *pañcāṅgas* could use different parameters or local conventions, and disputes over dates remained possible. The printed calendar nevertheless changed scale: calendrical authority became a commodity that could be purchased annually, annotated and retained. In Mithila, where learned traditions of *vyōtiṣa* and manuscript culture were strong, almanac publication helped connect specialist calculation with a broad reading public. Oral announcement, family memory and priestly consultation continued alongside print.

24.29 Modern state holidays, media and migration have created new layers of calendrical culture

Railways, schools, offices, broadcast media, mobile phones and migration have transformed how festival dates are known and enacted. A date once coordinated mainly through local specialists can now be circulated instantly across continents. Chhath provides a striking example: migration has reproduced the festival in distant cities, where access to water, public permits and work schedules reshape practice. State-sponsored cultural festivals can also reframe local traditions as regional heritage. These developments do not make the rituals inauthentic; they show that calendars are institutional technologies capable of travelling. At the same time, official recognition can privilege some festivals over others. The modern ritual year is therefore shaped by government calendars, media visibility and diaspora organisation as well as inherited lunar rules.

24.30 Conclusion: calendrical culture repeatedly turns cosmic cycles into social coordination

From Vedic ritual timing and early renunciant lunar observances to *pañcāṅga* calculation and the dense modern festival year of Mithila, the central historical process is the conversion of recurrent natural cycles into organised human time. The moon, sun, seasons and monsoon provide observable rhythms; institutions classify them; specialists calculate them; households embody them through fasting, cooking, gifts and travel; markets respond; sacred places fill and empty according to schedule. Continuity lies most securely in calendrical structures—lunar fortnights, seasonal reckoning, recurring observance—while individual festivals must be dated on their own evidence. This distinction prevents both antiquarian exaggeration and the

dismissal of later regional creativity. The next chapter turns from annual recurrence to the temporal thresholds of individual lives: death, ancestors and life-cycle rites.

Table 24.1 — Evidence for festivals and calendrical culture, and limits of inference

Evidence / practice	What it supports	What it does not prove alone	Source control
Vedic new/full moon and seasonal rites	Early ritual coordination of lunar and seasonal cycles	A complete later regional festival calendar	Use textual history; do not map every prescription onto ancient Mithila
Vedāṅga Jyotiṣa	Formal lunisolar calculation, tithi/nakṣatra/seasonal reckoning	A secure single date or direct Videha provenance	Treat chronology as debated; use for history of calendrical technique
Buddhist uposatha and vassa	Recurring lunar assembly and monsoon-based monastic season	Identical practice at every monastery or period	Normative Vinaya evidence, compared with regional institutions
Jain rainy-season and Paryuṣaṇā rules	Annual restriction of mobility and concentrated lay-ascetic interaction	Exact antiquity of every later festival custom	Separate canonical discipline from later community practice
Inscriptions and eras	Dated donations, regnal/era chronology, legal memory	Popular observance of the same date	Distinguish year-era from lunar day system
Pañcāṅgas and almanacs	Specialist mediation of tithi, nakṣatra, muhūrta and festival dates	Mechanical control of all economic activity	Compare calculation with task-specific household choices
Ishii's Mithila annual-rite ethnography	Late-20th-century festival sequence, seasonality, women's vratas and regional comparison	Ancient origin of modern rites	Use as ethnographic evidence and compare with earlier sources
Davis on Sāmā-Cakevā	Detailed women-centred Maithil festival practice and interpretation	Unbroken antiquity from Purāṇic narrative	Secure modern/recent history; earlier stages require independent evidence
Modern Chhath practice	Regional solar-facing observance scheduled by lunar date; household/public labour	Direct continuity from ancient sun worship	Distinguish ancient solar cult from historical development of present festival

Chapter 25 — Death, ancestors and life-cycle rites

Chapter argument. Life-cycle rites do not simply preserve an unchanged religious system from antiquity to the present. They convert biological events—conception, birth, maturation, marriage, ageing and death—into socially recognised transitions, and their forms change with household structure, inheritance, gender, ritual authority, religious affiliation and historical period. Mortuary practice is especially revealing because it brings body, kinship, property, memory and sacred geography together. The chapter therefore separates Vedic and domestic ritual texts, Buddhist and Jain traditions, archaeological evidence, and later Mithila practice before asking where continuity, transformation or retrospective invention can actually be demonstrated.

25.1 Life-cycle rites transform biological events into social transitions

Birth and death happen to bodies, but societies decide how those events become publicly intelligible. A newborn may receive a name, food, hair-cutting or initiation at prescribed stages; a marriage reorganises kinship, residence, sexuality and property; death changes a person into a corpse, a remembered ancestor, a relic-bearing saint or an absent legal subject depending on the institution involved. The concept of *saṃskāra* is useful for tracing Brahmanical life-cycle rites, but it should not be treated as a universal description of every community in Mithila, Vajji and Aṅga. Buddhist, Jain, non-elite and local practices followed different ritual logics, while many household actions never entered normative texts. Social history therefore begins not from a fixed list of rites but from the transitions that households and institutions had to manage.

25.2 Six evidence problems make mortuary history unusually difficult

Mortuary evidence is fragmentary for different reasons. Prescriptive texts tell us what specialists thought should be done, not how every household acted. Narrative texts can preserve powerful memories without providing contemporary ethnography. Cremation destroys much of the body and often leaves a weaker archaeological signature than formal burial. Monuments preserve exceptional persons and institutions more readily than ordinary households. Later ritual manuals may systematise practices centuries after their first appearance. Modern ethnography documents living traditions but cannot by itself date their origins. These problems are especially important in a region where rivers shift, settlements have been rebuilt repeatedly, and cremation grounds may lie outside excavated urban cores. The safest method is to date each evidence stream independently and treat convergence as stronger than resemblance alone.

25.3 The classical list of *saṃskāras* is itself a historical construction

Later Dharma and ritual literature presents life as a sequence of purifying and status-making rites, but the number and importance of those rites vary across texts and periods. Prenatal rites, birth ceremonies, naming, first feeding, tonsure, initiation, return from studentship, marriage and funeral are not all equally ancient, equally widespread or equally accessible. Some become markers of twice-born male status; others are household rites in which women play central roles; still others are absent or transformed in Buddhist and Jain settings. Treating the later canonical list as if it were a census of early Videha would erase both chronological development and social inequality. The history of rites must therefore ask when a rite is textually visible, who is authorised to perform it, and what social relationship it creates.

25.4 Rigvedic funerary hymns reveal both cremation and an ancestor-oriented imagination

Rigveda 10.16 addresses Agni as the fire that should prepare the deceased and send him toward the Fathers, while other mortuary hymns refer to the earth, the grave and the world of the ancestors. This already warns against a simple evolutionary story in which burial was first and cremation suddenly replaced it everywhere. Early Indo-Aryan mortuary imagination contained several ways of conceptualising bodily disposal and post-mortem destination. The Fathers are not merely remembered dead; they constitute a morally and ritually significant collectivity to which the deceased can be joined. Yet these hymns belong to a Vedic poetic-ritual corpus and cannot be localised automatically to early Mithila. Their value for this volume lies in defining a ritual vocabulary that later eastern traditions received, altered and embedded in new social landscapes.

25.5 The Śatapatha Brāhmaṇa makes the mortuary landscape itself part of ritual order

Book 13 of the Śatapatha Brāhmaṇa gives detailed instructions concerning the burial place or śmaśāna, its timing, location and construction. The text is especially important for a history of Videha because the Śatapatha tradition is deeply connected with the eastward Vedic world examined in earlier chapters. Even so, a ritual prescription is not an archaeological site plan. Its instructions show learned concern with the proper spatial and temporal separation of the dead, the Fathers and the living. They also show that commemoration could involve a durable place rather than only the moment of cremation. This combination of body disposal, delayed memorialisation and ancestor symbolism helps explain why later mortuary landscapes could accumulate social memory without implying that every household built a monumental tomb.

Evidence streams for life-cycle and mortuary history

Figure 96 — Life-cycle and mortuary history requires separate textual, archaeological and later-practice evidence streams before historical synthesis.

25.6 Fire transformed the corpse while also reorganising relations among the living

Cremation is a bodily technology, but its social effects extend beyond the pyre. Fuel must be obtained, the body transported, participants assembled, ritual competence mobilised and the remains handled. The role of fire in Vedic funeral ritual marks a transformation from the dangerous or liminal corpse toward an ancestral destination. Later domestic texts elaborate sequences before, during and after cremation. Such elaboration creates work for kin and specialists and imposes temporal obligations on the bereaved. Economic capacity therefore matters: access to fuel, cloth, vessels, transport and ritual services can differentiate mortuary practice even where normative texts describe one ideal sequence. The historical question is not simply whether people cremated their dead, but how disposal was organised, who bore its costs, and what social relationships the rite made visible.

25.7 Bone collection and memorialisation show that cremation does not erase materiality

Cremation may appear to destroy the body, yet many South Asian mortuary systems re-materialise the dead through ash, bone fragments, urns, memorial places or ancestor offerings. Domestic ritual texts describe post-cremation handling of remains, while Buddhist relic traditions make the surviving bodily fragment the centre of monumental cult. Archaeology must therefore look not only for complete skeletons but also for ash deposits, urns, relic caskets, mounds and structured deposits. The meanings of these materials differ sharply: a household bone deposit is not equivalent to a Buddhist relic stupa, and a Vedic burial mound is not automatically a shrine. What they share is a refusal to reduce death to disappearance. The body can continue socially in fragmented, relocated and ritually reclassified forms.

25.8 Mourning and impurity regulate the temporary disorder produced by death

Death interrupts ordinary household routines. Later Dharma literature codifies periods of impurity, restrictions on food and ritual, bathing, shaving and the gradual restoration of normality. These rules are often differentiated by kinship distance, status and circumstance of death. Their social function is not exhausted by ideas of pollution. They define who counts as close kin, who must suspend normal activity, and when a household can re-enter ordinary ritual and economic life. Because the detailed durations in later texts cannot be projected unchanged into early Videha, they are best used to identify a durable problem—how the living manage a period in which the dead person is no longer socially present but has not yet been fully incorporated into ancestral memory.

25.9 Ancestors convert genealogy into a continuing moral and ritual relationship

Ancestor rites make the dead relevant to the living through recurring acts of feeding, remembrance and obligation. The Vedic Fathers, later śrāddha traditions and household genealogical memory are not identical institutions, but all connect descent to ritual action. This relationship can stabilise lineage claims because remembered forebears provide a framework for belonging, inheritance and marital boundaries. Yet ancestor systems also exclude: people without recognised descendants, servants, renouncers, migrants or those outside dominant kin structures may be remembered differently or not at all in elite sources. A social history of ancestors must therefore distinguish between normative patrilineal ideals and the wider emotional and practical worlds in which mothers, daughters, affines, teachers and religious communities also sustain memory.

25.10 Śrāddha became a major technology for incorporating the dead among the ancestors

Gṛhya and Dharma traditions systematise offerings to the dead and the Fathers, including rites that move the recently deceased from the unstable condition of preta toward incorporation among the pitṛs. The exact sequence and terminology vary, but the broader structure is historically important: death creates a transitional social status that ritual resolves over time. Offerings of food and water, participation of descendants and the presence of ritual specialists turn memory into repeated practice. This also produces an economy of obligation, because commemorative meals, gifts and specialist services require resources. Later Mithila developed highly elaborated forms of śrāddha, but their documented complexity should not be read back wholesale into the early historic period. What can be traced more safely is the gradual textualisation of ancestor-feeding and kin-based commemoration.

Death as a social process

Property • ritual specialists • gender • status • local ecology

These factors can shape every stage.

Figure 97 — Death unfolds as a social process involving the body, kin, disposal, property, specialists and subsequent memory rather than as a single ritual moment.

25.11 Birth rites demonstrate that life-cycle ritual begins by making a new person socially legible

At the opposite end of life, prenatal and birth rites address vulnerability, fertility, naming and household continuity. Later saṃskāra systems distinguish rites associated with conception, pregnancy, birth and the first days of life. Their prescriptions reveal concerns with descent and the production of legitimate heirs, but they do not describe every birth in society. Women's bodily labour, midwifery and household care are much less visible than male-authored ritual rules. This imbalance matters for Mithila's social history. A lineage can celebrate the arrival of an heir while the physical risk of childbirth is borne by women whose knowledge may circulate orally rather than textually. Birth ritual should therefore be read alongside the history of gender, medicine and household labour developed in earlier chapters.

25.12 Naming, first feeding and hair rites organise childhood as a sequence rather than an undifferentiated stage

Classical domestic ritual texts mark several thresholds after birth: naming, first outing, first solid food and hair cutting among them. These rites matter historically because they create publicly recognisable stages of childhood. They also show that the social person is assembled gradually through kin recognition, diet, bodily modification and household participation. The timing and performance of these rites vary considerably, and later regional custom cannot be assumed for ancient Videha. Nevertheless, the very multiplication of childhood thresholds indicates increasing ritual attention to age and household reproduction. Such rites may also differentiate children by gender, lineage status or access to specialist ritual, reminding us that childhood was never a single uniform social experience.

25.13 Initiation made education, ritual entitlement and male status intersect

Upanayana becomes one of the most consequential Brahmanical rites because it links age with disciplined study and ritual eligibility. Its development is therefore relevant not only to religion but also to Chapter 17's history of education. Later normative systems distinguish eligible varṇa groups and prescribe different ages or details, creating a ritual mechanism for social differentiation. It would be anachronistic to impose the fully elaborated later scheme on early Videha, but the connection between initiation and access to authoritative knowledge is historically significant. In Buddhist and Jain communities, ordination created alternative forms of disciplined status that could cut across household life. Life-cycle history thus intersects with competing institutions of education and renunciation.

25.14 Marriage is both a life-cycle rite and a reorganisation of kinship, property and residence

Marriage occupies a central place in later saṃskāra systems because it joins two individuals while also creating relations between households. Gift exchange, residence, sexual legitimacy, inheritance, ritual partnership and future descent are all implicated. The ritual cannot therefore be separated from the social history of property and gender. Marriage forms also vary historically, and normative typologies should not be confused with statistical reality. In Mithila, later marriage regulation and genealogical institutions became especially elaborate, but those belong to later chapters and cannot be projected into the early historic period. For Chapter 25, the important point is structural: a wedding transforms networks of obligation and creates the descendants who may later perform ancestor rites, linking marriage directly to mortuary continuity.

25.15 Women's positions in life-cycle ritual cannot be reconstructed from male prescriptions alone

Normative texts often organise rites around patrilineal continuity and male ritual agents, yet women are indispensable to reproduction, marriage alliance, mourning and household memory. The Rgvedic funeral corpus is also important because a verse in 10.18 addresses the widow or women beside the dead and directs a return toward the world of the living; it should not be used as simple proof that widow immolation was a universal Vedic funeral requirement. Later widowhood practices, including extreme forms such as sati in some periods and regions, have their own histories. The methodological rule is therefore strict: gendered mortuary practices must be dated independently, and later customs cannot be back-projected into Vedic or early Videha merely because later interpreters sought ancient sanction.

25.16 Death is also a property event because rights and obligations must outlive the deceased

A death can redistribute land, livestock, debts, ritual duties, guardianship and household authority. Normative legal texts discuss inheritance in increasingly elaborate terms, but even before such codification the practical problem is unavoidable: who controls resources when a household member dies? Mortuary rites can legitimise succession by publicly identifying close kin and demonstrating their obligations. Ancestor worship then gives descent a continuing ritual form. This is one reason death rituals can become socially conservative, reinforcing lineage boundaries and ranked access to property. At the same time, widows, daughters, younger sons, dependants and religious institutions may contest or redirect inheritance. The chapter therefore treats property not as an external economic topic but as one of the material mechanisms through which death changes social structure.

25.17 Ritual specialists turn life-cycle knowledge into a form of service and authority

As rites become textually complex, households depend on specialists who know sequences, mantras, calendrical timing and rules of purity. This creates both authority and livelihood. Priests may receive gifts; barbers, potters, washermen, cooks, transporters or other occupational specialists can also become indispensable in later regional ritual systems. Their exact roles vary greatly by period and locality, so a modern service list cannot be projected into early Mithila. The broader historical mechanism is nevertheless clear: life-cycle rites distribute work beyond the immediate family. Ritual knowledge can become hereditary or professionalised, while households demonstrate status by the scale of services they mobilise. This connects mortuary history directly to occupational differentiation and the service economy.

25.18 Buddhist mortuary practice shifted emphasis without eliminating social ritual around death

Early Buddhism rejected the idea that liberation depended on Vedic sacrifice to ancestors, yet Buddhist communities did not become ritually indifferent to death. Texts discuss dying, cremation, relics, memorial monuments and the transfer or dedication of merit. Monastic discipline also had to regulate illness, death and possessions within the Saṅgha. The result is not a simple opposition between “ritual Hinduism” and “non-ritual Buddhism.” Rather, Buddhism reorganised the social meaning of death. The deceased monk, nun, teacher or Buddha could become an object of communal memory, and lay donors could support memorial practices. In regions such as Vajji, where Buddhist institutions were embedded in cities and political communities, death could therefore generate durable public monuments as well as private grief.

25.19 The Mahāparinibbāna tradition makes cremation, political claim and relic division one connected social drama

Dīgha Nikāya 16 describes the Buddha’s death at Kusinārā, the preparation and cremation of the body, and the subsequent dispute over the relics. The narrative is valuable not because every detail can be treated as a contemporary administrative record, but because it shows how bodily remains could become politically and ritually meaningful. Claimants justify their right to a share through identity and status; a mediator divides the relics; recipients promise monuments and commemorative observance. Death thus becomes a moment when territory, community reputation and sacred memory are renegotiated. For this volume, the most important regional claimant is the Licchavi polity of Vesālī, whose participation links a major Vajjian centre directly to the history of Buddhist relic culture.

25.20 The Licchavi claim to the Buddha's relics gave Vaiśālī a mortuary memory of exceptional durability

The Mahāparinibbāna Sutta states that the Licchavis of Vesālī sought and received a share of the Buddha's remains and built a stupa. This tradition differs sharply from household ancestor rites: the deceased is not incorporated into a lineage of Fathers but materialised as a universally significant teacher whose relics can sanctify a polity. Yet the social mechanism has parallels with ancestor memory. A fragment of the dead body anchors collective identity in place, attracts repeated commemoration and creates obligations of maintenance. Vaiśālī thereby offers unusually strong evidence for the transformation of death into civic sacred geography. The later history of the site demonstrates how a mortuary event can outlive the political community that first claimed the relic.

Vaiśālī: from cremation relic to civic sacred memory

Textual memory and the excavated monument are separate evidence streams.
They converge on Vaiśālī as a major relic centre.

Figure 98 — The Vaiśālī relic tradition links cremation, Licchavi political claim, relic division and monumental commemoration while keeping textual memory and archaeology analytically distinct.

25.21 The excavated Vaiśālī relic stupa gives material evidence independent of the literary narrative

Excavations conducted under the K. P. Jayaswal Research Institute in 1958–1962 uncovered the relic stupa at Vaiśālī and a stone casket containing ashy earth together with small objects. Government and archaeological descriptions identify an early mud core subsequently enlarged and encased. The excavation does not prove every episode of Dīgha Nikāya 16, nor can each object in the casket be securely assigned to the moment of the Buddha's death. Its importance is more disciplined: it demonstrates a long-lived relic monument at the centre named by Buddhist tradition and provides physical evidence for repeated construction and veneration. Text and archaeology therefore converge at the level of place and relic cult while remaining independent in chronology and detail.

25.22 Relic monuments turn the dead into institutions that require labour, patronage and repeated visitation

A stupa is not only a container. Once built, it requires land, construction material, maintenance and social recognition. Visitors bring offerings; institutions organise access; rulers may rebuild or embellish the

monument; artisans reproduce its forms. The deceased person's body can thus enter an economy of memory. Gregory Schopen's work on Buddhist inscriptions and monastic archaeology has shown how closely death, merit, donors and monastic institutions could be connected. Vaiśālī provides an early regional anchor for that larger pattern, while later Buddhist sites in Bihar make it more visible epigraphically. The historical lesson is that mortuary material can reorganise living communities for centuries after the original death.

25.23 Buddhist merit practices broadened remembrance beyond biological descent

Buddhist social life created ways to remember the dead that did not depend exclusively on patrilineal ancestor ritual. Gifts to monasteries, stupa worship and merit-making could be directed toward deceased relatives, teachers or wider communities. This does not mean kinship disappeared; donors frequently acted from family motives. The difference is institutional. Monastic communities offered a durable recipient for gifts, and inscriptions in later periods show monks and nuns themselves participating in memorial and merit practices. The possibility of linking the dead to a religious corporation diversified the social destinations of wealth and memory. In Mithila, Vajji and Aṅga, this helps explain how renunciant institutions could become embedded within household economies rather than remaining outside them.

25.24 Jain traditions made disciplined dying a distinctive ascetic problem, not a general household funeral rule

Jain texts place exceptional emphasis on the ethical management of bodily action and attachment. Sallekhanā—the gradual thinning of passions and, in appropriate circumstances, food at the approach of death—became a recognised ascetic and lay ideal in Jain tradition. It must be handled carefully in social history. It is not a synonym for every Jain death, and modern legal debates over santhara cannot be projected back unchanged onto early Vaiśālī. The practice belongs to a specific ethical framework of non-attachment and karmic discipline. For the region associated in Jain memory with Mahāvīra, its importance lies in showing that religious traditions could construct the good death differently: not primarily as ancestor incorporation or relic production, but as a final discipline of conduct and consciousness.

25.25 Jain household mortuary practice is less visible in early regional evidence than Jain ascetic ideals

The textual prominence of monks, vows and exemplary deaths can create a distorted picture in which ordinary Jain households seem absent. In reality, lay communities had to bury or cremate relatives, mourn, inherit property and sustain social ties like other households. Early evidence for the precise regional forms of these practices is limited. The correct response is not to fill the gap with later custom. Instead, the historian should distinguish the well-attested Jain ethical discourse on dying from the less securely documented household mortuary repertoire of early Vajji and Videha. This distinction parallels the wider method of the volume: institutional visibility is not the same as demographic universality.

25.26 Archaeology rarely permits the religion or community of an ordinary cremation to be identified confidently

Unlike inscribed relic monuments, ordinary cremation deposits are difficult to assign to a named religious group. Ash, burnt bone, pottery or an isolated burial may show disposal practice, but without inscriptions or distinctive context they do not identify the deceased as Vedic, Buddhist, Jain or adherent of a local tradition. This is especially important at multi-religious urban centres such as Vaiśālī and Campā. Excavation can reveal

settlement density, monuments and material culture while leaving household death nearly invisible. The absence of cemeteries in an excavated sector therefore does not prove absence of mortuary practice. Cremation grounds may lie beyond habitation, river erosion may destroy them, and later construction may erase traces. Archaeological silence must be interpreted as a preservation problem before it becomes a social conclusion.

25.27 Rivers and water connect mortuary practice to ecology, mobility and sacred geography

Water is repeatedly used in purification, offerings and the handling of remains, while rivers can become destinations for ashes or commemorative journeys in later Hindu practice. The Ganga therefore matters to the mortuary history of Aṅga and the wider middle Gangetic region, but chronology is essential. The fact that modern families immerse ashes in a sacred river does not prove that every ancient resident of Campā followed the same procedure. What can be said more securely is that riverine environments shaped access, transport and the possible preservation or dispersal of remains. Water also links death to the sacred geography discussed in Chapter 23: once a riverbank becomes a recognised mortuary or pilgrimage place, repeated ritual use can generate markets, specialist services and collective memory.

Life-cycle rites link persons to social institutions

Related, not uniform: chronology, gender, status and community alter their form.

Figure 99 — Life-cycle rites connect persons and households to childhood, marriage, death, property, specialists and wider kin institutions, but their forms vary by chronology and community.

25.28 Later Mithila developed dense life-cycle ritual systems, but their antiquity must be demonstrated rather than presumed

Later textual, genealogical and ethnographic evidence from Mithila records highly structured marriage, birth, mourning and ancestor practices. Such material is indispensable for the medieval and modern social history of the region, especially when read alongside Pāñji institutions and changing caste formation. It is also dangerous if used as a shortcut to antiquity. A rite recorded in a nineteenth- or twentieth-century Maithil household may preserve older elements, but continuity requires evidence of transmission, not merely similarity to a Sanskrit text. The same rule applies to specialist roles and caste-labelled services. In accordance with this volume's governing method, later social classifications—including Śrottriya as a distinct sub-caste—will not be projected backward into periods where the evidence does not support them.

25.29 Continuity is most persuasive at the level of recurring social problems, not identical ritual scripts

Across two and a half millennia, households repeatedly confronted the same broad transitions: a child had to be incorporated, marriages had to create recognised relationships, deaths had to be managed, property had to pass, and memory had to be sustained. It is reasonable to identify these as durable social problems. It is much harder to prove that the same mantra, sequence, specialist or caste role continued unchanged. Historical continuity therefore exists at several scales. The need to mourn may be continuous while the mourning period changes; ancestor remembrance may persist while its ritual technology is transformed; a sacred place may endure while the institution that controls it changes. This layered approach avoids both extremes—imagining complete rupture at every period and inventing an unbroken timeless tradition.

25.30 Conclusion: death and life-cycle rites reveal how society reproduces itself across generations

Life-cycle rites are among the clearest places where intimate bodily events become public social history. Vedic mortuary texts show cremation, burial memory and the Fathers; domestic ritual literature increasingly orders the transitions of birth, initiation, marriage and death; Buddhism transforms the dead body into relic, merit and monument; Jain traditions articulate a distinctive ethic of disciplined dying; archaeology at Vaiśālī gives material form to one exceptional relic history; later Mithila develops dense regional systems of marriage and ancestor ritual whose chronology must be studied rather than assumed. Across these traditions, death is never only an ending. It redistributes property, activates kinship, creates memory, employs specialists and sometimes produces sacred places. Life-cycle history therefore explains how societies reproduce themselves not only biologically, but institutionally and symbolically across generations.

Table 25.1 — Evidence for death, ancestors and life-cycle rites, and limits of inference

Evidence / practice	What it supports	What it does not prove alone	Source control
Rigveda 10.16 and 10.18	Early mortuary language concerning fire, the dead, the Fathers and return of survivors to the living	A uniform funeral practice for all communities of early Mithila	Jamison & Brereton; Rigvedic corpus
Śatapatha Brāhmaṇa XIII.8	Learned concern with burial ground, memorial timing and the relation between dead and Fathers	An excavated map of actual Videhan cemeteries	Eggeling; Śatapatha Brāhmaṇa
Gṛhya/Dharma ritual texts	Increasing codification of saṃskāras, funeral procedure, impurity and śrāddha	Universal performance or unchanged chronology	Oldenberg; Kane; Pandey; Michaels
Mahāparinibbāna tradition	Cremation, relic division, Licchavi claim and memorial stupa at Vesālī	Exact archaeological dating of every narrative episode	Dīgha Nikāya 16; Strong
Vaiśālī relic stupa	Material relic monument, casket and successive building history	Proof that every casket object belongs to the Buddha's original cremation	Sinha & Roy; Bihar/NMA site records

Evidence / practice	What it supports	What it does not prove alone	Source control
Buddhist monastic/epigraphic evidence	Merit, memorialisation and institutional care for the dead beyond biological descent	That all lay funerals followed monastic patterns	Schopen; Buddhist inscriptions
Jain textual traditions	Ethics of dying, renunciation and sallekhanā in Jain religious thought	A universal Jain household funeral custom in early Vaiśālī	Jaini; Dundas; Jacobi
Archaeological absence of burials	Limits created by cremation, site location, erosion and preservation	Absence of mortuary practice	Contextual archaeological method
Later Mithila ethnography and ritual manuals	Detailed regional practice, specialist roles and household memory in documented periods	Automatic continuity back to Vedic or early historic times	Pandey; regional ethnography; source dating

PART IV

EARLY MEDIEVAL AND MEDIEVAL SOCIAL TRANSFORMATION

Chapters 26–35

Chapter 26 — Land Grants and Changing Agrarian Society

Land grants are among the most informative written records for the social and economic history of early medieval eastern India, but they are also among the easiest to overread. A copper-plate charter can describe a village, its boundaries and resources, the dues attached to it, the exemptions granted to a beneficiary, the officials and residents who were notified, and the religious or scholarly purpose of the donation. It does not, by itself, reveal the acreage actually cultivated, the proportion of households affected, the everyday bargaining power of cultivators, or the long-term success of the grant. This chapter therefore treats land grants as legal and fiscal interventions into agrarian society rather than as transparent photographs of village life. For Mithila–Tirabhukti and the Aṅga–Mudgagiri zone, the surviving charters are especially valuable because they can be located within identifiable administrative landscapes and compared across several centuries.

26.1 The problem: land, rights and documentary evidence

Modern language often compresses a land grant into the statement that a king ‘gave a village’. The charters are more precise and more complicated. What could be transferred included claims to revenue, rights over specified resources, immunities from particular royal demands, authority to receive payments from residents, and in some cases judicial or policing privileges. The physical soil, the cultivators’ labour, the king’s fiscal claims and the beneficiary’s rights were not identical things. Historians therefore need to ask what exactly changed hands in each record. The wording of a grant is also formulaic. Repeated phrases are evidence for chancery practice and legal expectations, but their repetition does not prove that every listed privilege was enforced identically in every locality. The method adopted here is to read formula, geography, recipient, revenue terms and local society separately before asking how they combined.

26.2 Copper plates as durable legal instruments

Copper plates were not simply commemorative inscriptions. Their durability, seals, boundary clauses, lists of rights and warnings to future rulers gave them the character of documentary titles. The record could memorialise a royal order, a purchase followed by donation, or a ratified transfer. The Nandapur plate from the Munger district, dated Gupta year 169 (488 CE), shows how procedural this documentary world could be: an official wishing to acquire uncultivated land had to petition, pay the customary price, obtain verification from record-keepers, have the plot measured and bounded, and receive a copper-plate instrument. Such evidence cautions against imagining an abrupt medieval invention of landed documentation. The early medieval charters developed out of older administrative and legal practices while expanding the range and political importance of enduring grants.

LAND GRANTS: DISTINCT EVIDENCE STREAMS

Figure 100 — Land grants: distinct evidence streams

26.3 The Nandapur antecedent in the Munger region

The Nandapur charter is especially useful because its logic differs from a later royal donation of an already constituted village. The applicant sought four kulyavāpas of uncultivated land, paid eight dīnāras at the local customary rate, and intended to donate the land to a Sāmavedic Brahman for the regular performance of the five great sacrifices. Record-keepers checked that the land was revenue-free and that its sale did not injure royal interest. Survey and boundary marking were expressly required. This is evidence for priced land, documentary procedure and the administrative distinction between cultivated holdings and uncultivated land. It is not evidence that all agrarian land was freely alienable in a modern market. Rather, it reveals a controlled transaction in which local custom, public record and royal fiscal interest converged.

26.4 From sale-and-gift procedure to royal śāsana

Across the following centuries, copper-plate charters increasingly present the king or a king-ratified donor as creating a durable śāsana. The change should not be reduced to a simple passage from private property to ‘feudal’ property. The documents show several forms: direct royal donation, requests by petitioner-donors, confirmation of transfers, and grants made from holdings associated with officers or magnates. Sanjukta Datta’s work on Pāla charters has stressed the role of petitioner-donors who could initiate a transfer while royal authority validated it. This is important for social history. A charter was a meeting point between court, intermediary, beneficiary and local residents. Its legal force came from the polity, but its social consequences depended on already inhabited and worked landscapes.

26.5 Tirabhukti as an administrative landscape

Tirabhukti appears repeatedly in inscriptions as an administrative frame for north Bihar. It should not be treated as perfectly coterminous with any modern map of Mithila, yet it is one of the strongest period terms available for locating agrarian administration. Grants refer to subordinate units such as viṣaya, maṇḍala and village localities. These names matter because land was never donated in an abstract cultural region; the charter located rights within a hierarchy of jurisdictions and notified officials and residents. The recurrence of Tirabhukti in records from different dynastic contexts also shows institutional continuity across political

change. At the same time, boundaries and administrative reach changed, and a findspot outside Tīrabhukti does not mean that the donated land lay at the findspot.

26.6 The Pāla charter system

Pāla copper plates from the eighth to twelfth centuries developed a recognisable documentary form: royal genealogy and praise, the place of issue, an address to officials and residents, identification of the granted property, the beneficiary and purpose, specification of fiscal rights and exemptions, a command to inhabitants, and verses demanding future protection of the gift. The large official lists are evidence for the state's imagined administrative reach, but should not be converted mechanically into an organisation chart in which every named office was active in every village. More securely, the lists show that a grant was meant to be communicated across several levels of authority. The charter publicly reclassified claims on a locality and stated who was henceforth entitled to receive specified dues.

26.7 Mudgagiri/Munger as a place of issue

Mudgagiri, identified with Munger, was an important Pāla jaya-skandhāvāra or victorious camp from which charters were issued. Devapāla's Munger plate, dated to his regnal year 33, records the grant of the village Meśikā in Kṛmilā-viṣaya of Śrīnagara-bhukti to a Brahman. A later Nālandā charter of Devapāla was also issued from Mudgagiri and granted five villages for the support of a monastery at Nālandā. These examples demonstrate that the place from which a ruler issued a charter, the findspot of the plate and the location of the donated property could be different. For the history of Aṅga and adjacent zones, Munger's importance lies partly in its function as a political-administrative node connecting royal movement, the Ganga corridor and documentary transactions over land elsewhere.

26.8 The Bhagalpur plate of Nārāyaṇapāla

The Bhagalpur copper plate of Nārāyaṇapāla, regnal year 17, is the chapter's central regional case because its findspot lies in Bhagalpur while the charter was issued from Mudgagiri and concerns property in Tīrabhukti. It records the grant of Makutikā village to a Śiva temple or sacred establishment at Kalaśapeta/Kalāsapota and to an assembly of Pāśupata scholars. The endowment was meant to sustain worship, offerings, charitable feeding, construction, bedding, seats and provision for medicine required by the sick. The record therefore joins agrarian revenue to an institutional economy. It also warns against treating dynastic religious identity as exclusive: a Pāla ruler conventionally styled as a Buddhist sovereign could support a Śaiva establishment through a royal land grant.

BHAGALPUR PLATE: WHAT A GRANT TRANSFERRED

Figure 101 — The Bhagalpur plate: a bundle of agrarian and institutional rights

26.9 A village as a bundle of ecological resources

The Bhagalpur charter does not define Makutikā merely as cropped acreage. Its formula includes boundaries, grass and pasture, flat and raised land, mango and mahua trees, watering places, ditches and saline or otherwise unproductive ground. Similar clauses recur in other Pāla records. Formulaic repetition matters, but the list is still socially revealing: the fiscal object called a ‘village’ encompassed multiple ecological niches and resources. Pasture connected cultivation to cattle; trees yielded food, fodder, oil, timber or other products; water shaped both agriculture and settlement; waste, pits or saline ground could carry future value. Agrarian history must therefore include common-use and non-plough resources rather than treating the countryside as a field of grain alone.

26.10 Bhāga, bhoga, kara and hiraṇya

Pāla charters frequently transfer or redirect dues expressed through terms such as bhāga, bhoga, kara and hiraṇya. Their precise meaning could vary by place and period. Bhāga is commonly associated with a share of produce; kara is a general tax term; bhoga can denote provisions or other dues; hiraṇya points to a monetary or cash-valued component in many interpretations. The safest conclusion is not to assign one immutable modern tax category to each word. What the charters clearly show is a bundle of claims that normally flowed toward political authority and could be reassigned to a beneficiary. The social meaning of the grant therefore lay at least partly in changing the destination and authority of extraction rather than in physically moving land.

26.11 Exemptions and the reach of officials

The same grants that transfer revenue often proclaim relief from specified burdens. A-cāṭa-bhaṭa-praveśa clauses exclude entry by cāṭas and bhaṭas, categories generally connected with state agents or troops. Other formulas concern additional imposts, fines, policing and freedom from ‘all burdens’. These clauses have sometimes been read as the state surrendering sovereignty. That inference is too strong. Exemption itself presupposed a sovereign authority capable of defining what was being exempted and of commanding subordinates to respect the new arrangement. Yet the exemptions could materially alter village experience by

limiting ordinary demands from itinerant officials or military personnel and by strengthening the beneficiary's position within the local field of authority.

26.12 Fines, theft and local coercive authority

Several charters transfer rights connected with fines for specified offences and with the apprehension of thieves. Such clauses complicate any narrow description of grants as 'tax-free land'. Fiscal privilege and coercive jurisdiction could overlap. The beneficiary might gain claims that affected dispute, policing or punishment, while the crown retained the higher framework in which those privileges were authorised. The practical extent of local judicial power cannot be reconstructed from formula alone, but its appearance in charters is evidence that agrarian control involved more than rents. It included the capacity to command, to exclude some officials, and in some circumstances to benefit from or administer penalties.

26.13 Resident cultivators and the change of payee

The Bhagalpur and Bangaon grants both address resident cultivators. The Bangaon plate states that cultivators should deliver the appropriate *bhāga*, *bhoga*, *kara*, *hiraṇya* and related dues at the proper time after becoming obedient to the donee's order. This is among the clearest points at which a royal charter touches everyday agrarian society. The text does not say that cultivators were transferred as chattel, nor does it document the terms of every tenancy. It does show that existing residents were expected to recognise a new fiscal authority. A grant could therefore change the social relation between producing households and the person or institution entitled to claims on their surplus.

26.14 Religious endowments as agrarian institutions

Temples, monasteries and communities of learned specialists depended on material support. Land grants converted flows from agrarian production into worship, teaching, maintenance, food, medicine, construction and hospitality. This did not make religious institutions economically separate from villages; it embedded them in rural production. The Bhagalpur grant is unusually explicit about the uses of the endowment, including care for the sick. Devapāla's Nālandā grant, outside the immediate core but useful comparatively, supported monks, manuscript copying and monastery maintenance through five villages. These cases demonstrate how agrarian surplus could be institutionally channelled into religious and intellectual life.

26.15 Royal religion and plural patronage

Pāla rulers are often described through Buddhist titles and invocations, but their grants do not support a model of sectarian exclusivity. Nārāyaṇapāla's Bhagalpur charter benefits a Śaiva/Pāśupata establishment. The social historian should separate royal self-presentation, personal devotion, political legitimation and actual patterns of endowment. Supporting different institutions could integrate learned communities, ritual centres and local elites into a wider political order. The evidence is more useful for reconstructing networks of patronage than for assigning a whole territory a single religious identity. It also shows that land grants were part of the material history of religious plurality discussed in earlier chapters.

26.16 The Bangaon plate of Vigrahapāla III

The Bangaon copper plate of Vigrahapāla III, regnal year 17, found at Bangaon in present Saharsa district, places Vasukāvartha in Hodreya-*viṣaya* of Tīra-bhukti. It grants a defined share of land to the Brahman Ghaṇṭūkaśarman. The charter again lists the property with boundaries, grass and pasture, trees,

water, pits or saline land, exemptions, policing rights and the revenue bundle of bhāga, bhoga, kara and hiranya. It is particularly important because its regional location brings the legal language of Pāla grants directly into north Bihar. The record also preserves details about learned migration, lineage and settlement that allow agrarian history to be connected with intellectual and social mobility.

26.17 Ghaṇṭūkaśarman and scholarly mobility

Ghaṇṭūkaśarman is described through gotra, pravara, Vedic affiliation and scholarly accomplishments in mīmāṃsā, grammar and reasoning. His family is associated with migration from Kolāñca and residence at Iṭṭāhaka. Such biographical clauses were part of the beneficiary's credentialing and should not be treated as a census of Brahman migration. Nevertheless, they provide concrete evidence that grants could support the relocation or consolidation of learned households and that scholarly reputation was linked to landed endowment. This mobility belongs to the social history of medieval Mithila, but it does not justify projecting later Maithil Brahman sub-caste structures backward into the Pāla period.

26.18 The bhūmicchidra-nyāya formula

The phrase bhūmicchidra-nyāya appears in Pāla grants and is often translated through the idea of land reclamation or entitlement associated with bringing uncultivated land into use. It has been central to arguments that land grants drove agrarian expansion. The formula is important, but it cannot prove that every granted village was virgin land newly cleared by the beneficiary. The same charter may concern inhabited places with resident cultivators. A safer reading is that reclamation language supplied a legal principle for durable enjoyment and fiscal privilege, while actual local conditions ranged from uncultivated tracts to established settlements. Archaeology and environmental evidence are needed before converting legal formula into a literal history of forest clearance.

26.19 The Bagaha grants and the Gandak zone

Two copper-plate charters found at Bagaha in Champaran and dated 1020 and 1026 CE record grants by Saurāditya of the Malayaketu family. The 1020 charter grants Vanapalli-grāma, located in Vyalisi-viṣaya within Daradgaṇḍakī-maṇḍala, to the Brahman Yaśāditya. The record is important because it shows a non-Pāla ruling house issuing landed endowments within the broader Tirabhukti sphere. Early medieval agrarian change was therefore not the work of one dynasty. Local and sub-regional powers participated in the same documentary culture, using grants to bind religious merit, learned beneficiaries and territorial authority together.

SELECTED REGIONAL LAND-GRANT NODES

schematic — not to scale

*Figure 102 — Selected regional land-grant nodes and documentary connections***26.20 Donor plurality and intermediary power**

Not every grant originated as a king's spontaneous gift. Petitioner-donors, ministers, local magnates and subordinate rulers could initiate or materially enable transfers that the king ratified. The Bangaon record itself contains additional verses concerning Ghaṇṭīśa, a figure connected to the donated tract and to the creation of a śāsana from his own plough-land. Such material warns against a two-actor model of king and peasant. Between court and cultivator stood officials, landed intermediaries, Brahman households, temple or monastic managers and local notables. Their relative power varied, but charters show them participating in the redistribution of fiscal claims and in the documentary definition of rural space.

26.21 Land measurement, boundaries and memory

A grant required the land to be made recognisable. Earlier transactions such as Nandapur specify measurement and durable boundary markers; later charters frequently invoke the property up to its established limits and list attached resources. Boundary making transformed landscape into legal description. Trees, water, paths, embankments, neighbouring plots and settlement names could become part of a durable documentary memory. Because rivers shifted and place names changed, the historian must resist false precision when identifying every medieval locality on a modern map. The important social point is that rights were stabilised through collectively intelligible markers and records, even in dynamic alluvial landscapes.

26.22 Agrarian expansion without a single mechanism

Land grants could accompany agricultural expansion, but expansion had multiple agents. Cultivators cleared and reclaimed land; pastoral and forest-using communities negotiated or lost access; local chiefs and religious institutions sought revenue; rulers encouraged settlement; and existing villages could be reassigned without major new clearance. The Nandapur sale of uncultivated land provides direct evidence for bringing waste into a permanent endowment. By contrast, the Pāla charters' references to resident cultivators demonstrate that some grants reorganised established production. Regional agrarian growth should therefore

be reconstructed as a combination of extension, intensification, reclassification and redistribution rather than as one continuous march of plough agriculture into empty forest.

26.23 Forests, wetlands and the fiction of empty land

Terms translated as waste, uncultivated or non-arable do not mean socially unused. Wetlands, grazing grounds, groves, scrub and seasonal flood zones could support fishing, fodder collection, hunting, craft materials, transport or shifting cultivation. Legal documents are written from the perspective of taxable and grantable resources; they can obscure uses that did not fit that frame. This is especially important in north Bihar's riverine environment and in the forest-upland margins toward Añga and Munger. Agrarian expansion could create new production while also reducing flexible access to commons. The charters rarely allow the historian to identify who lost such access, so this consequence must be posed as a question rather than asserted as a documented outcome in every case.

26.24 Peasant agency and the silence of charters

Cultivators appear in grants primarily as people who are informed, commanded or required to render dues. This is an archival imbalance, not proof that they lacked agency. Farmers could change cropping patterns, resist demands, migrate, negotiate with intermediaries, use kinship and village institutions, or exploit environmental mobility. Those actions are much less likely to be preserved in royal copper plates. The historian must therefore avoid turning the charter's command language into a complete social description. The record establishes an intended legal order; everyday agrarian relations had to make that order workable. Later evidence on village communities and disputes can illuminate possible mechanisms, but it should not be projected backward without period control.

26.25 Women, households and landed production

The surviving charters are overwhelmingly male-centred in their named donors, officials and beneficiaries. That documentary pattern cannot be equated with an exclusively male agrarian economy. Cultivation, animal care, food processing, storage, textile work, collection of fuel and fodder, and household management all depended on women's labour, although royal grants rarely enumerate it. Nor should the absence of women as named recipients in a particular regional sample be generalised into a universal legal incapacity. The chapter therefore treats gender as a structural silence in the charter archive: indispensable to production, but under-recorded in the surviving instruments through which rulers described land and revenue.

26.26 Social classification without retrospective caste projection

Pāla charters can list Brahmins, mahattamas, kuṭumbins and named occupational or social categories among the residents to whom royal orders were announced. Beneficiaries may be described by gotra, pravara and Vedic school. This evidence is valuable for the formation of hierarchy and learned communities, but it does not authorise the projection of later caste taxonomies backward. In particular, the later Maithil category Śrotriya must not be inserted into the Pāla-period record as a fixed Brahmin sub-caste. The charters show historically specific forms of Brahmin status, migration and landed privilege; the later organisation of Maithil Brahmin society belongs to a different evidentiary and chronological problem.

26.27 Land grants and the “Indian feudalism” debate

R. S. Sharma made land grants central to a model of Indian feudalism, emphasising the transfer of fiscal and administrative rights, the growth of intermediaries and changing conditions of peasants. Harbans Mukhia challenged the applicability of European feudal categories to Indian history, while B. D. Chattopadhyaya redirected attention toward regional state formation, settlement, markets and political process. More recent studies, including Ryosuke Furui’s work on eastern India, reconstruct changing land relations without assuming that one label resolves the evidence. For this volume, ‘feudalism’ is therefore treated as a historiographical hypothesis, not a fact built into the sources. Each regional charter is first analysed in its own legal, ecological and social context.

AGRARIAN CHANGE: A CONTROLLED MODEL

Figure 103 — Agrarian change through land grants: a controlled analytical model

26.28 Grants, money and markets

Land-grant expansion should not automatically be equated with the disappearance of money or markets. The Nandapur transaction itself values uncultivated land in *dīnāras*. Pāla charters use fiscal terms that include *hiranya*, often linked with monetary payment or cash valuation. Religious institutions supported by villages could purchase goods, employ labour and participate in wider exchange. Chapter 15 showed that monetisation was uneven rather than all-or-nothing; the same principle applies here. A society could redirect agrarian revenues through landed endowments while retaining market exchange and monetary practices. The relationship between grants and commerce must be demonstrated regionally, not deduced from a general model of economic decline.

26.29 Mithila–Tirabhukti and Āṅga–Mudgagiri in one documentary zone

The strongest regional lesson comes from reading charters relationally. Mudgagiri/Munger served as a place of issue for Pāla grants; the Bhagalpur plate found in the Āṅga zone concerns a village in Tirabhukti; the Bargaon plate documents a grant within north Bihar; Bagaha records show local rulers making grants along the Gandak side of Tirabhukti. These movements of plates, orders, beneficiaries and revenues cut across the modern habit of treating Mithila, Āṅga and Magadha as sealed compartments. Yet connectivity must not erase difference. The ecology, political history and density of surviving records vary across these zones. A connected documentary field is not the same as a uniform agrarian system.

26.30 Conclusion: from grant to agrarian society

Early medieval land grants changed agrarian society not because a copper plate magically created cultivation, but because documentary authority could redirect revenue, define exemptions, privilege institutions, credential learned beneficiaries and reorder the obligations of residents. The surviving evidence shows both continuity with earlier land-sale procedures and new scales of royal and intermediary endowment. It also reveals the limits of the archive: cultivator voices, women's work, informal access to commons and local negotiation remain only partially visible. The most defensible history therefore moves from document to relationship, not from formula to stereotype. Chapter 27 follows these transformations into the connected spaces of village, market and town, where agrarian surplus, exchange and settlement hierarchy can be examined together.

Table 26.1 — Selected evidence for land grants and agrarian change, with limits of inference

Evidence	What it supports	Limit of inference	Source control
Nandapur plate, Gupta year 169 (488 CE), Munger district	Purchase of uncultivated land at a customary <i>dīnāra</i> price; record-keeper verification; measurement and permanent endowment	Does not show that all land was marketable or that later village grants worked identically	DHARMA Nandapur Plate; N. G. Majumdar
Jivagupta Tirabhukti charter (date/dynastic attribution debated)	Grant of localities with water, trees, pits/barren land and royal dues to a <i>Cāmuṇḍā</i> temple; administrative officers and Tirabhukti geography	Dating and ruler identification are uncertain; formula does not equal observed village practice	D. C. Sircar, "Copper-Plate Grants from Bihar"; Inscriptions of Bihar
Devapāla Munger plate, regnal year 33	Mudgagiri as issuing camp; grant of <i>Meśikā</i> village to a Brahman; Pāla charter form	Donated village lay outside the immediate Munger find/issue locality	DHARMA Munger Plate; Kielhorn; Barnett
Nārāyaṇapāla Bhagalpur plate, regnal year 17	Makutikā village in Tirabhukti granted for a Śiva/Pāśupata establishment; taxes, exemptions, resources and cultivator dues specified	Bhagalpur findspot does not locate Makutikā in Bhagalpur; formula cannot quantify extraction	DHARMA Bhagalpur Plate; Inscriptions of Bihar
Vigrahapāla III Bargaon plate, regnal year 17	Vasukāvartta in Hodreya- <i>viṣaya</i> of Tirabhukti; Brahman beneficiary; resident cultivators to render dues	Does not prove wholesale replacement of local population or a later Maithil caste system	DHARMA Bargaon Plate; Sircar, Epigraphia Indica 29
Saurāditya Bagaha plate, Vikrama 1077 / 1020 CE	Vanapalli in Daradgaṇḍakī- <i>maṇḍala</i> granted to a Brahman by a sub-regional ruler	One grant cannot define all Gandak-zone settlement or polity	Indian Archaeology 1960–61; Sircar, Epigraphia Indica 35
Nālandā plate of Devapāla (comparative control)	Five villages endowed for monastery maintenance, monks and manuscript copying	Outside the core regional focus; used to clarify institutional economy, not to generalise local conditions	DHARMA Nalanda Plate; Hirananda Sastri

Evidence	What it supports	Limit of inference	Source control
Historiographical models	Land grants can illuminate agrarian expansion, intermediaries, state formation and institutional patronage	No single model—especially “feudalism”—should be treated as self-proving	Sharma; Mukhia; Chattopadhyaya; Furui

Chapter 27 — Village, Market and Town

Settlement history is the study of relationships among people, production, exchange, institutions and movement. Early medieval eastern India cannot be reduced either to a landscape of self-sufficient villages or to an unbroken survival of ancient cities. The evidence instead shows differentiated settlements connected by fiscal orders, markets, rivers, roads, courts and religious institutions. For Mithila, Vajji and Aṅga, the documentary record is strongest for villages and administrative geography, while Mudgagiri/Munger and Antichak/Vikramaśīla provide important non-rural anchors. Comparative evidence from the wider Pāla–Sena world helps identify market and merchant forms without pretending that every feature is locally attested. The chapter therefore reconstructs a controlled village–market–town continuum and keeps the limits of inference visible.

27.1 Settlement categories as historical relationships

The words village, market and town appear deceptively simple because modern administration gives each a relatively familiar meaning. Early medieval evidence is less tidy. A grāma could be a revenue-bearing settlement, a cluster of households, a named territorial unit in a grant, or a community whose fields, groves, pasture and water extended well beyond a compact habitation. A market could be a regular haṭṭa, a point of exchange attached to a road or river crossing, or a commercial function operating within a settlement named by some other term. A town might be recognised through political headquarters, dense construction, specialised production, institutional concentration or long-distance connections, even when an inscription does not label it nagara. This chapter therefore treats settlement categories relationally. The central question is not whether a place fits a modern checklist, but how households, cultivators, traders, institutions and officials moved goods, labour, revenue and information among differently scaled nodes.

27.2 The vocabulary: grāma, haṭṭa, pura, nagara and caturaka

Early medieval inscriptions and texts use a vocabulary of settlement whose terms cannot be translated mechanically. Grāma normally points toward a village or rural settlement, yet the economic weight of one grāma could differ sharply from another. Pura and nagara carry urban associations, but literary convention can magnify their splendour. Haṭṭa denotes a market and is especially valuable because it identifies a commercial function rather than only settlement size. Twelfth-century eastern Indian records also attest caturaka, literally associated with a four-way convergence and interpreted as a settlement form intermediate between village and major town. Such evidence is strongest in Bengal and is used here comparatively, not to claim that every named category is directly attested in Mithila or Aṅga. The vocabulary nevertheless demonstrates that early medieval settlement was differentiated. Rural residence, exchange, administration and transport could combine in multiple ways, producing a continuum rather than a binary opposition between isolated village and fully urban city.

27.3 The village was not a self-sufficient cell

Land-grant historiography once encouraged the image of the early medieval village as an increasingly self-contained unit, especially when grants transferred revenue rights to religious beneficiaries and intermediaries. The charters themselves complicate such an image. They refer to payments, shares, cash-related dues, officers, neighbours, roads, watercourses, pasture, trees and boundaries; they assume communication between royal authority, local residents and beneficiaries. A village that paid dues, supplied institutions, obtained metal goods, salt or cloth, and participated in marriage, pilgrimage or seasonal labour was already embedded in

networks beyond its fields. Self-provisioning could remain important without eliminating exchange. Nor did a village require a daily market to be commercially connected: itinerant traders, periodic markets, fairs and nearby nodes could integrate dispersed households into wider circuits. The analytical mistake is to confuse the predominance of agriculture with economic isolation. Rural production formed the base of many networks precisely because towns, courts and monasteries required dependable flows of grain, oil, fibre, animals and labour.

27.4 Villages in the Tīrabhukti charter landscape

The Pāla records discussed in Chapter 26 provide the clearest documentary window onto rural settlement in north Bihar. Tīrabhukti appears as an administrative frame containing viṣayas, smaller units and named grāmas. The Bangaon plate of Vīgrahapāla III, found in present Saharsa district, places granted land within this layered geography and addresses residents who were expected to recognise the transfer. The Bhagalpur plate of Nārāyaṇapāla links a charter found in the Aṅga zone with a grant concerning property in Tīrabhukti. These documents do not give a census of settlement or a map of market frequency, but they reveal a political landscape in which villages were legible to administration. Revenue could be assigned, boundaries remembered, residents notified and obligations redirected. That bureaucratic legibility itself depended on routes of communication. The village was therefore simultaneously a place of production and a node in documentary, fiscal and institutional systems extending well beyond the locality.

27.5 Fields, groves, pasture and water as settlement infrastructure

A village was more than houses surrounded by cropped land. The Bhagalpur and related eastern Indian charters list or imply grassland, pasture, groves, trees, water, raised and low ground, ditches and areas of differing productivity. These resources shaped settlement size, seasonality and exchange. Cattle required grazing and access to water; mahua and mango trees supplied food, fodder, drink, shade and marketable produce; wetlands could sustain fishing and aquatic resources; higher ground mattered in flood-prone country. A settlement with mixed ecological assets could support more varied livelihoods than one dependent on a single crop. Such diversity also generated exchange among households and localities. The language of boundaries, while created for legal security, thus preserves fragments of an economic landscape. It warns against drawing a village as a compact dot on a map. In the alluvial plains of Mithila and the riverine environment of Aṅga, settlement space was a mosaic of habitation, fields, commons, seasonal water and movement corridors.

27.6 Households, kuṭumbins and local notables

Inscriptions frequently address collective categories such as mahattamas, kuṭumbins, cultivators and other residents. These labels should not be translated into fixed modern classes without contextual study, but they show differentiation within rural society. Some households controlled more land, cattle, labour or local influence than others. Certain residents could witness transactions, mediate boundaries or help communicate royal orders. The household remained a critical unit of production, consumption and intergenerational transfer, yet village decisions could involve hierarchies among households. This mattered for markets. Better-resourced cultivators were more able to generate saleable surplus, extend credit, hire labour or transport produce. Poorer households might sell labour, craft output or small quantities of produce under less favourable conditions. The emergence of market exchange therefore did not erase rural hierarchy; it could amplify it. Chapter 28 examines occupational and service communities directly, but settlement history already shows why their location and access to patrons mattered.

27.7 Why markets emerge in agrarian landscapes

Markets become useful when households cannot or do not wish to produce everything they consume and when producers need outlets for surplus. In early medieval eastern India, the relevant goods ranged from grain, oil, pulses, livestock and forest products to salt, cloth, metal implements, pottery and ritual materials. Institutions created concentrated demand, while royal camps and administrative centres required supplies that could not be met by a single estate. Markets also reduced the cost of finding buyers and sellers by concentrating exchange in time and space. Yet the surviving evidence rarely measures transaction volume. A haṭṭa in an inscription proves a recognised market function, not the number of stalls or whether it operated daily. The correct inference is therefore functional: a market linked local production to wider circuits, enabled price comparison, attracted transport and service activity, and gave merchants a point from which to aggregate rural goods or distribute items produced elsewhere.

27.8 The haṭṭa and the problem of periodicity

The term haṭṭa is widely associated with a market in early medieval eastern Indian records. Modern eastern India contains many weekly or twice-weekly haats, but that ethnographic familiarity must not be projected backward automatically. The historical evidence often does not specify frequency. What it does establish is that some commercial places were distinct enough to be named, taxed, endowed or incorporated into merchant activity. Periodic operation would have been well suited to dispersed rural settlement because traders and consumers could converge on fixed days without supporting permanent shops every day, but the hypothesis must be tested case by case. Market periodicity also interacts with agricultural seasonality. Harvest months create surpluses and purchasing power; monsoon conditions alter road access; religious festivals can increase temporary demand. Thus the haṭṭa should be understood less as a miniature modern town than as a flexible institution connecting rural cycles to broader exchange.

27.9 Merchant organisation: a comparative eastern Indian control

The Rajbhita stone inscription of the time of Mahīpāla I, from the wider Pāla world of Bengal, records a vaṇiggrāma, an organised body of merchants, associated with three haṭṭas. Ryosuke Furui has used this evidence to argue against a simple narrative in which merchants disappear with early medieval ruralisation. The case is comparative rather than local to Mithila–Aṅga, but it is highly relevant because the Pāla political sphere crossed Bihar and Bengal. It shows that merchants could be rooted in rural space and organised around multiple market nodes. The term vaṇiggrāma should not be translated literally as proof of a 'merchant village'; it refers to a mercantile collectivity. Its significance lies in institutional organisation. Merchants could coordinate obligations and activity across more than one market. Such evidence suggests that ruralisation and commerce were not mutually exclusive: commercial groups could adapt to landscapes in which exchange was distributed among local centres rather than concentrated only in ancient metropolitan cities.

27.10 Figure 104 and the logic of reciprocal flows

Figure 104 summarises the chapter's basic model. Agricultural villages supplied food, raw materials, animals and labour; markets aggregated some of these goods and redistributed salt, cloth, tools and other necessities; larger towns and institutional nodes concentrated administration, specialised services and demand. The arrows run both ways. Towns did not merely drain villages. They returned manufactured goods, credit, information, religious services, legal authority and opportunities for employment. Markets likewise depended on rural purchasing power while affecting rural production decisions. This reciprocal

model avoids two errors: treating the village as isolated, and treating the town as an autonomous engine disconnected from its hinterland. The intensity of flows changed with harvests, floods, political security and institutional fortunes. A historically useful settlement hierarchy is therefore dynamic. A place could rise when a court, monastery, ferry or route attracted activity and decline when that function shifted elsewhere.

Figure 104 — Village, market and town: reciprocal flows

27.11 Rivers, crossings and the geography of exchange

Mithila, Vajji and Āṅga were structured by major rivers and by the practical difficulty of crossing them. The Ganga offered a longitudinal corridor but also a barrier requiring boats, landing places and seasonal judgement. North Bihar's Gandak, Kosi and other channels linked and divided communities in ways that changed with avulsion and flood. A ferry point could become an exchange node because travellers, carts, officials and merchants converged while waiting to cross. Yet geography does not prove commerce by itself. A river adjacent to a settlement is evidence of transport potential, not of documented trade volume. Historical claims must be tied to itineraries, inscriptions, archaeological distributions or explicit references to routes and markets. The most defensible model is one of opportunity constrained by season, technology and political security. Water transport could lower bulk-transport costs, while changed channels could strand an older landing or redirect movement toward a new node.

27.12 Mudgagiri/Munger as an administrative town

Mudgagiri, identified with Munger, provides the strongest regional example of an early medieval settlement whose importance cannot be reduced to agriculture. Pāla copper plates were issued from a jaya-skandhāvāra at Mudgagiri, and recent inscriptional and sculptural research has reinforced its role as a royal administrative headquarters. A place that hosted the court or a major royal camp generated demand for food, animals, craft goods, scribal work, religious services and transport. Officials and petitioners had reasons to travel there; documents issued there could affect distant villages. This is precisely the kind of nodal function that makes a town historically important even when the archaeological footprint of ordinary housing is incompletely known. Mudgagiri also sat on the Ganga, strengthening its connectivity without allowing us to assume a fixed port infrastructure. Its evidence combines political centrality, religious patronage and regional movement—an urban function created through institutions as much as through commerce.

27.13 The town as a place of documentary power

Early medieval towns often concentrated the personnel who converted political authority into documents. Copper-plate charters required petitions, scribes, engravers, seals, witnesses and channels for communicating the result to local officials and residents. Sanjukta Datta's work on Pāla charters shows that donors and petitioners could play active roles in securing royal ratification. A headquarters such as Mudgagiri therefore participated in a circulation of paper-like information even when the surviving legal instrument was copper. Villages entered the town's field of power through tax assignments and orders; the town depended on villages for the resources that sustained court and administration. This relationship illustrates why settlement history must include institutions. Urbanity was partly an ability to organise transactions at a scale larger than one locality. A royal camp could be mobile in origin yet produce durable urban functions when offices, religious establishments, craft specialists and supply networks clustered around it.

27.14 Antichak/Vikramaśīla as an institutional node

The excavated complex at Antichak in Bhagalpur district, generally identified with Vikramaśīla Mahāvihāra, adds a different kind of large settlement function. Excavations revealed an extensive brick monastery with numerous cells, a central shrine and associated structures. The site demonstrates a concentration of resident and visiting persons requiring food, fuel, cloth, manuscripts, building materials, ritual objects and maintenance. Archaeology cannot by itself reconstruct the exact market system that supplied these needs, and later literary descriptions should not be read as direct account books. Nevertheless, an institution of such scale had a hinterland. Grain and other necessities had to move toward it; people moved for learning, patronage and religious purposes; artisans participated in construction and repair. Vikramaśīla therefore belongs in settlement history not because a monastery automatically equals a town, but because a major institution could generate town-like demand and connectivity in the Aṅga-Bhagalpur landscape.

Figure 105 — Regional nodes in the early medieval landscape

27.15 Monasteries, temples and the redistribution of surplus

Religious institutions received land, produce, cash, labour and gifts. Some of that support was consumed locally; some financed construction, ritual, teaching, hospitality and maintenance. The economic effect was redistributive. A monastery or temple could draw agrarian surplus from granted villages and return demand for food processing, transport, craft production and services. It could also attract pilgrims or students whose presence increased exchange. This does not mean every religious centre became an urban centre. Scale, duration, route access and political patronage mattered. Nor should institutional landholding be assumed to impoverish nearby markets; its effects varied. In some contexts, a large endowed institution created regular demand and encouraged specialised production. In others, concentration of rights could burden cultivators or redirect surplus away from alternative uses. The settlement historian must therefore ask what an institution did in its local economy rather than classify it by religious identity alone.

27.16 Tīrabhukti and the problem of a missing urban archaeology

North Bihar's early medieval documentary record is stronger for administrative geography and land grants than for excavated urban sequences. This imbalance matters. It would be easy either to assume that old centres such as Vaiśālī continued unchanged or to infer that towns vanished because the inscriptions emphasise villages. Neither conclusion follows. Ancient urban sites can contract, shift or acquire new functions; new centres can grow without inheriting famous ancient names. Tīrabhukti should therefore be reconstructed as a landscape of villages, administrative loci, religious centres and routes whose exact settlement hierarchy remains partly unknown. The absence of a fully excavated early medieval town in a given district is not positive evidence of an exclusively rural economy. It is an archaeological and research gap. This chapter keeps those gaps visible rather than filling them with retrospective maps of later Darbhanga, Janakpur or other urban centres.

27.17 Small nodes: ferries, crossroads and service concentrations

Between village and major town were many possible intermediate nodes. A ferry landing, crossroads, temple cluster, administrative station or market could accumulate services without becoming a large walled city. Comparative eastern Indian evidence for *caturaka* in the twelfth century is particularly useful because it identifies a settlement form associated with the meeting of roads and standing between ordinary village and major town. Such categories remind us that settlement hierarchy was granular. A blacksmith, oil-presser, potter, money-handler or innkeeper benefited from locations where customers converged. These nodes could be seasonal or modest in population yet economically important. They also made long journeys possible by breaking routes into manageable stages. The strongest claims require direct evidence, but the concept of intermediate nodes prevents a false map containing only countless villages and a few capitals.

27.18 Craft production and the location of specialists

Craft production could occur inside villages, at market nodes or in towns. Potters often needed clay and fuel near consumers; metalworkers needed access to raw metal, charcoal and repair demand; textile production could be household-based yet connected to merchants who supplied inputs or collected cloth. Archaeological craft debris is especially valuable because it can identify production beyond elite texts, but preservation is uneven. A concentration of specialised workshops may signal urban activity, whereas scattered household production can remain thoroughly rural. The same occupation might therefore appear in different settlement contexts. The location of craft specialists depended on market size, patronage, transport costs and social organisation. Chapter 28 examines occupational communities, but the settlement perspective

already reveals a key point: specialisation is not synonymous with urban residence. Markets can connect rural specialists to broader demand, while large institutions can draw craftsmen temporarily for construction and repair.

Figure 106 — The haṭṭa as a rural-commercial interface

27.19 Grain, storage and the feeding of non-cultivators

A town or large monastery could not exist without dependable food supply. The relevant historical process is not simply 'surplus extraction' but collection, storage, transport and redistribution. Grain is bulky and vulnerable to moisture, pests and spoilage; moving it requires containers, carts, boats, animals and labour. Oil, ghee, salt and pulses have different storage characteristics. Institutions could receive produce as dues or gifts, while markets allowed producers and intermediaries to convert commodities. Archaeological storage features are rarely sufficient to reconstruct the whole system, and charter formulas do not tell us the quantities delivered. Nonetheless, the existence of substantial non-cultivating populations implies organised provisioning. This is a crucial bridge between village and town. Urban demand gave rural surplus a destination, while failures of harvest, transport or political security could quickly expose the dependence of concentrated populations on their hinterlands.

27.20 Money, credit and transactions

Chapter 15 distinguished monetisation from the mere presence of coins, and the same caution applies here. Early medieval markets could conduct transactions through coin, weighed metal, produce, credit or mixed forms of payment. The relative shares are rarely recoverable. Land-grant records that mention *hiranya* or earlier transactions valued in *dīnāras* show that money-related concepts persisted, but they do not prove that every village purchase was monetised. Merchants could extend credit; institutions could receive produce directly; wages could combine food and cash. John Deyell's work on early medieval north Indian monetary history and the wider debate on 'monetary anaemia' warn against equating a reduced supply of high-value silver coin with the disappearance of exchange. Settlement networks could function through multiple media. The historical question is therefore practical: what forms of value allowed goods and obligations to move between households, markets and larger nodes?

27.21 Taxes, tolls and the fiscal visibility of exchange

Markets and towns attracted political attention because exchange could be taxed or regulated. Early medieval records from different regions refer to levies on trade, market dues, ferries and transit, although the precise fiscal vocabulary and institutional arrangements vary. The Pāla charters of Bihar are more explicit about agrarian dues than about a complete commercial tax system, so one should not import western Indian *mandapikā* structures into Mithila or Aṅga without evidence. Still, the principle is clear: concentrated exchange creates points where authorities can count, police or claim a share. Conversely, grants of exemptions could shift the beneficiary of such revenue. Fiscal visibility can therefore make markets appear disproportionately in inscriptions. A market named in a document was not necessarily the largest commercial place; it was a place relevant to the legal or fiscal transaction being recorded.

27.22 Land grants did not automatically kill markets

The spread of land grants is central to the debate over early medieval urban change. R. S. Sharma linked grants, declining long-distance trade and the growth of landed intermediaries to urban decay. B. D. Chattopadhyaya and later scholarship emphasised regional variation, new forms of trade and the growth of different urban centres. Eastern Indian evidence supports caution toward a single line of decline. Grants could redirect surplus to monasteries and temples that themselves generated demand. Merchant groups could operate in rural markets. Administrative headquarters such as Mudgagiri retained nodal importance. At the same time, some ancient towns undoubtedly contracted and certain long-distance circuits changed. The correct model is transformation with uneven outcomes. Land grants altered control over resources, but their effect on settlement depended on how beneficiaries consumed, invested and redistributed those resources, and on the wider conditions of transport and trade.

27.23 The urban-decay debate and the evidence from eastern India

Sharma's Urban Decay in India remains important because it forced historians to compare archaeological strata, craft production, coinage and trade rather than assume continuous urban prosperity. Its strength is the insistence that towns can decline materially. Its weakness, when applied too broadly, is the risk of making decline the default explanation for every region between the Gupta and Sultanate periods. Chattopadhyaya's work on trade and urban centres instead draws attention to new nodes, settlement forms and processes of urbanisation. Furui's research on Bengal adds a further complication: merchants could reorganise within rural environments, and market activity did not require the survival of an earlier urban elite in unchanged form. For Mithila, Vajji and Aṅga, the evidence favours a plural history—contraction at some old sites, persistence or transformation at others, and the rise of politically or institutionally anchored centres such as Mudgagiri and Vikramaśīla.

27.24 Archaeology: what would demonstrate a town?

Calling a settlement a town should ideally rest on converging evidence. Dense and long-lived construction, streets or drainage, concentrations of craft debris, seals and sealings, storage, fortification, religious monuments, imported goods and a hinterland relationship can all contribute. No single feature is sufficient. A monastery with monumental architecture may be institutionally specialised rather than a general-purpose town; a fort may house a garrison without a broad market; a large pottery scatter may reflect production rather than urban residence. Figure 107 therefore sets out an evidence-control model. Textual labels, archaeology, institutional scale and connectivity should be compared. This approach is particularly necessary in north Bihar, where river movement, sedimentation and modern settlement can obscure

archaeological remains. The absence of excavated streets cannot be filled by the fame of a name in later literature.

Figure 107 — How to infer settlement hierarchy without overclaiming

27.25 Women and the hidden geography of exchange

Inscriptions naming donors, officials and merchants are heavily male-centred, but household and market economies depended on labour that such texts rarely individualise. Women participated in cultivation, animal care, food processing, spinning, preparation of goods for exchange and management of household stores; the exact division of work varied by community and period. Some women also appear as donors in early and medieval Indian epigraphy, though the regional record is uneven. A settlement history built only from named male office-holders would therefore understate the labour behind marketable surplus. At the same time, one should not romanticise market participation as equal access. Property rights, mobility, household authority and social status shaped who could travel, negotiate prices or control earnings. The invisibility of many women in charters is an archival limitation, not evidence of economic absence.

27.26 Inequality within and between settlements

Settlement hierarchy was also a hierarchy of opportunity. A household close to a market or ferry could sell perishable goods more easily than one separated by difficult seasonal roads. A town resident might have better access to patrons, credit and information but depend on purchased food and rent. Villages located on fertile land or near institutional estates could accumulate resources, while flood-prone or marginal settlements faced greater risk. Political privilege mattered as well: grants could exempt some beneficiaries from dues while leaving producers responsible for payments. Towns could concentrate wealth without eliminating poverty. Markets could widen choice while exposing poorer sellers to debt and adverse prices. The social history of settlement must therefore track who benefited from connectivity and who carried its costs.

27.27 Seasonality, flood and the changing map of access

A road or market route in the alluvial plains was not equally usable throughout the year. Monsoon rain, river floods, waterlogging and channel shifts altered travel times and transport choices. Boats could become more useful when roads deteriorated, yet dangerous currents could make crossings harder. Harvest seasons changed the volume and direction of commodity movement. Dry-season fairs or pilgrimage could temporarily increase traffic at nodes otherwise modest in scale. Settlement hierarchy was therefore partly seasonal. A market's catchment could expand in one season and contract in another; a river landing could migrate; a road could be replaced by a raised embankment or alternative track. Long-term history must allow for this mobility. Static modern maps create a false impression of permanent routes across a dynamic floodplain.

27.28 The village–market–town continuum in Mithila, Vajji and Āṅga

The evidence assembled here supports a continuum model. Tīrabhukti's charters make villages administratively visible; the Ganga and its crossings provided potential corridors; Mudgagiri concentrated royal and documentary functions; Antichak/Vikramaśīla concentrated institutional demand in the Bhagalpur–Āṅga zone; eastern Indian inscriptions show that merchant groups and haṭṭas could operate within broadly rural settings. None of these elements by itself yields a complete regional urban system. Together they demonstrate that settlement functions were differentiated and connected. A village could participate in markets without becoming a town. A market could become a local service centre without acquiring monumental architecture. A politically favoured node could grow rapidly and later contract. The continuum is therefore not a linear evolutionary sequence but a field of changing functions.

27.29 Methodological rules for reconstructing settlement networks

Five rules follow. First, use historical settlement terms as evidence, not as fixed modern categories. Second, distinguish the existence of a market from claims about its frequency or volume. Third, require converging evidence before assigning urban status. Fourth, map routes as period-specific possibilities shaped by rivers, roads, institutions and political security rather than as timeless lines. Fifth, treat famous later towns cautiously when earlier archaeological or documentary continuity is unproven. These rules help prevent both romantic continuity and exaggerated decline. They also make the gaps productive: where evidence is missing, the correct statement is that the settlement hierarchy remains uncertain. A history designed to avoid placeholders must resist filling those uncertainties with confident-sounding but unsupported detail.

27.30 Conclusion: settlements as a network of social dependence

Early medieval society in Mithila, Vajji and Āṅga was predominantly agrarian, but agrarian does not mean isolated. Villages produced food, raw materials and labour; markets concentrated exchange; towns and major institutions organised administration, specialised services and demand. Mudgagiri and Vikramaśīla show two different ways in which non-rural functions could become regionally important. Pāla charters reveal the administrative legibility of villages, while comparative Bengal evidence demonstrates merchant organisation across rural markets. The resulting landscape was neither a continuous chain of flourishing ancient cities nor a closed world of self-sufficient villages. It was a shifting network whose nodes rose and fell with political power, institutional patronage, transport conditions and ecological change. Chapter 28 moves from places to people by examining labour, service and occupational communities within this connected settlement system.

Table 27.1 — Evidence for village, market and town, with limits of inference

Evidence	Regional / comparative example	What it supports	What it does not prove
Land-grant charters	Tirabhukti, Bangaon, Bhagalpur and related Pāla records	Named villages, administrative units, residents, dues, resources and documentary connections	Population size, market frequency or complete settlement hierarchy
Royal headquarters	Mudgagiri/Munger as Pāla jaya-skandhāvāra	Administrative concentration, court demand and supra-local movement	A fixed population total or fully excavated commercial quarter
Large institution	Antichak/Vikramaśīla in Bhagalpur district	Concentrated resident/visitor demand, monumental construction and hinterland provisioning	That a monastery was identical to a general-purpose town or that every supply passed through a formal market
Market terminology	Haṭṭa in early medieval eastern Indian inscriptions	Recognised market function and rural-commercial interfaces	Daily operation, exact trade volume or identical organisation in every region
Merchant organisation	Rajbhita vaṇiggrāma under Mahīpāla I (comparative Bengal evidence)	Merchants could organise across rural market nodes in the wider Pāla world	Direct proof of the same institution in Mithila or Aṅga
Settlement morphology	Archaeology: density, durable structures, craft debris, seals, storage, routes	Convergence of multiple urban functions	Urban status from one monument, one inscription or a famous place-name alone
Rivers and roads	Ganga and north-Bihar river crossings; route potential	Transport opportunities, ferry nodes and seasonal connectivity	Continuous use, fixed channels or quantified commercial traffic without additional evidence
Urban-change debate	Sharma, Chattopadhyaya, Furui and archaeological comparison	Regional transformation, contraction and new nodal forms can coexist	A universal model of either total urban collapse or uninterrupted prosperity

Chapter 28 — Labour, Service and Occupational Communities

Early medieval social history is often reconstructed from landholders, rulers and institutions because they dominate the written record. This chapter reverses the angle of vision. It asks who cultivated fields, carried messages, guarded roads, supervised ferries, made tools, carved images, copied documents, supplied monasteries and performed the countless services that turned rights on copper plates into functioning society. The evidence does not permit a complete occupational census. It does permit a controlled reconstruction of differentiated labour, service and skill—and of the gradual processes through which some livelihoods became more tightly organised as hereditary social groups.

28.1 Labour as a historical problem

Labour is easy to see in the results of production and difficult to see in the surviving texts. Fields were cleared and cultivated, embankments maintained, cattle tended, boats moved, pottery fired, metal repaired, images carved, documents copied and institutions fed. Yet royal charters usually record rights, beneficiaries and officials rather than the names and conditions of the people who performed most of this work. A social history of labour must therefore reconstruct relationships from several kinds of evidence instead of treating a list of occupational labels as a census. For Mithila, Vajji and Āṅga in the early medieval centuries, the best regional controls are Pāla-period charters from Munger and Bhagalpur, the archaeology of Antichak/Vikramaśīla, and material evidence from Mudgagiri. Wider eastern Indian inscriptions help identify possible patterns, but they cannot be imported wholesale into north Bihar.

28.2 Occupation, service, status and caste are not synonyms

A person's work, mode of dependence, social rank and later caste identity need not coincide. Kṣetrakara identifies cultivation more directly than it identifies a bounded caste. Sevaka denotes service but does not by itself tell us whether the service was domestic, military, administrative, temporary or hereditary. Terms such as mahattara and kuṭumbin point to rural standing and household position rather than a single occupation. Conversely, later normative texts may classify communities by inherited status even when earlier records reveal more fluid economic roles. This distinction is essential because early medieval history has often been written backwards from later caste ethnographies. The safer method is chronological: establish what a contemporary record actually names, identify the social relation implied by that term, and only then ask whether later evidence shows increasing heredity or closure.

28.3 Four evidence streams and their limits

Figure 108 separates four evidence streams. Copper-plate charters are strongest for administrative visibility: they list officials, residents, cultivators and groups whose compliance with a grant mattered. Archaeology reveals production without necessarily naming producers. Normative and literary texts preserve social categories, ideals and stereotypes, but they are not demographic surveys. Comparative work on eastern India can illuminate processes such as the gradual systematisation of occupational groups, yet regional timing varied. No single stream is sufficient. An iron object proves metal use, not the caste of the smith; an official title proves an office, not its lifetime tenure; a ranked social list proves a classificatory language, not the exact everyday relations among all people named. Labour history becomes reliable when these evidentiary limits are built into the argument rather than added as a final disclaimer.

28.4 The Bhagalpur plate as a social document

The Bhagalpur plate of Nārāyaṇapāla, issued in year 17, is especially valuable because its notification formula extends far beyond a royal elite. It addresses a long sequence of officers and servants and then turns to residents, describing a social field from Brahmans and leading persons down to Meda, Andhra and Caṇḍāla. The same grant requires resident cultivators to obey the new fiscal arrangement and deliver the appropriate shares and dues. This does not make the plate a complete map of society: the list is formulaic, status-laden and shaped by the legal purpose of transferring a village's revenues. Even so, it demonstrates that the grant was imagined as affecting people who cultivated, administered, policed, transported, served and inhabited the locality. A land grant was therefore also a reordering of obligations.

28.5 The Munger plate and the labour of administration

Devapāla's Munger plate of year 33 contains an equally revealing roster. Alongside high officers appear functionaries connected with punishment, policing, tolls, forts, frontiers, messaging, travel, ferries, animals and local administration. It then addresses residents led by mahattaras and kuṭumbins and extends the social range to groups including Meda, Andhraka and Caṇḍāla. The importance of the passage lies less in translating every title with false precision than in recognising the density of specialised service around royal government. Administrative power depended on labour: messages had to travel, revenue had to be assessed and moved, animals maintained, crossings supervised and coercion organised. The court and the countryside were connected by people performing these functions. Many of them may have been mobile; others were embedded in local society.

28.6 Cultivators and the base of the agrarian economy

The resident kṣetrakaras named in Pāla charters were the people whose cultivation made a revenue grant economically meaningful. They were not necessarily a homogeneous peasantry. Some may have held substantial household plots; others worked smaller holdings or land controlled through superior rights. The charter tells us that cultivators had obligations to render specified dues after a transfer, but it rarely tells us how labour was recruited within the household, whether hired workers were employed, or how harvest risk was shared. Ryosuke Furui's reconstruction of early medieval eastern India stresses increasing differentiation in land relations and the growth of larger holdings above actual cultivators. For the regional history of Mithila and Aṅga, this suggests a stratified agrarian world without allowing us to assign a single tenure status to every kṣetrakara.

28.7 Household labour and invisible cooperation

Much agricultural work took place within households. Ploughing, transplanting, weeding, harvesting, threshing, storage, animal care, fuel collection and food processing demanded coordinated labour across seasons. Charters normally name household heads or collective categories and therefore hide much of the work of women, children, dependants and junior kin. This invisibility should not be mistaken for absence. Agricultural manuals and comparative rural evidence show that successful cultivation required timed cooperation rather than the isolated activity of a male landholder. Household labour also linked production to reproduction: children learned skills, food was processed, tools maintained and animals cared for. The historical household was thus both a social and productive institution. Because the surviving sources distribute recognition unequally, a labour history must distinguish who worked from who appeared in legal documents.

28.8 Mahattaras, kuṭumbins and rural differentiation

Terms such as mahattara and kuṭumbin appear in early medieval eastern Indian records as indicators of rural standing. They should not be flattened into modern equivalents such as landlord, peasant proprietor or village elder in every context. Their importance here is relational. They occupied positions from which they could be notified, witness transactions, mediate boundaries or represent local interests, while poorer cultivators and labourers were less visible. This differentiation affected access to labour. Better-resourced households could command family labour, exchange work with neighbours, hire assistance or extend credit during agricultural bottlenecks. Less secure households might sell labour or accept unfavourable advances. The rural economy therefore contained unequal capacities to mobilise work. Those inequalities are more historically defensible than a simple division between free peasants and serfs.

28.9 Agrarian labour beyond the named cultivator

Actual field work could exceed the labour capacity of the household that held cultivation rights. Peak seasons created demand for additional hands, and larger holdings could only be managed through dependants, wage-like arrangements, share relations, attached labour or combinations of these. The evidence from Pāla north Bihar does not permit a numerical estimate of landless labourers, and the language of later agrarian systems should not be projected backwards. Nevertheless, the gap between legal control over land and the physical work required to cultivate it is historically significant. Where landholding became more stratified, the possibility of separating the manager or superior right-holder from the actual tiller increased. Furui's wider eastern Indian model places agrarian labourers at the lower end of increasingly layered land relations by the later early medieval period.

28.10 Figure 108: reconstructing labour without a false census

Figure 108 summarises the evidentiary method. Charters illuminate people made legible by fiscal and administrative transactions; archaeology illuminates the products and spaces of work; normative texts illuminate ranking and social ideology; comparative history helps identify processes whose regional presence must still be demonstrated. The convergence of these streams allows strong statements about specialised labour and differentiated social relations. It does not justify claims that every occupational group was already a closed caste or that every named status corresponded to one economic function. This distinction matters most for communities at the lower end of textual hierarchies, whose voices are rarely preserved in documents produced for courts, monasteries or Brahman beneficiaries.

Labour history: distinct evidence streams

Figure 108 — Labour history: distinct evidence streams

28.11 State service as an occupational world

The official rosters of the Munger and Bhagalpur plates reveal government as a large service complex. Beyond ministers and commanders were officers concerned with accounts, justice, policing, tolls, territorial supervision, forts, messengers, transport and animal resources. Some titles probably represented substantial offices; others may have denoted operational personnel or categories of royal retainers. Together they show that state formation generated work that was not directly agricultural. Administrative labour depended on literacy, numeracy, mobility, record keeping and coercive capacity. Mudgagiri/Munger, a Pāla jayaskandhāvāra, would have concentrated many such services when the royal camp or headquarters was present. The town's significance therefore included a labour market created by government itself—clerks, guards, suppliers, transporters, artisans and attendants serving an administrative centre.

28.12 Cāṭa, bhaṭa and sevaka: coercion and service

Pāla charters repeatedly refer to cāṭas, bhaṭas and sevakas, often in formulas that prohibit their entry into donated villages. The terms have been interpreted in relation to soldiers, police-like retainers and servants, but their precise institutional meanings could vary. The exemption formula is nevertheless revealing. Villagers experienced royal personnel not only as abstract authority but as bodies that could enter settlements, demand supplies, enforce orders or impose burdens. Excluding such entry enhanced the autonomy or privilege of the donee. From the standpoint of labour history, the formula also reminds us that military and service personnel had to be housed, fed and moved. State service redistributed demands onto rural producers even when the surviving charter presents the matter as a legal privilege.

28.13 Ferries, boats, messengers and animal handlers

The Pāla official lists include titles connected with ferries and with elephants, horses, camels, cattle and other animals, as well as messengers and personnel concerned with movement. In the riverine geography of Mithila, Vajji and Aṅga, these were not peripheral occupations. Crossing the Ganga or its tributaries required boats, landing places, skilled handling and local knowledge of currents and seasons. Royal communication depended on relays of people and animals. Armies and courts depended on fodder, stable work and

veterinary knowledge even when the texts do not individualise those workers. Transport labour linked agrarian villages to markets, administrative centres and religious institutions. It also carried risk: flood, channel change and seasonal scarcity could transform the value of local expertise.

28.14 Figure 109: the charter's social field

Figure 109 places the main categories visible in Pāla grants into three analytical zones: administrative service, rural society and ranked social classification. The zones overlap. A local notable might also serve the state; a cultivator might transport produce; a person placed low in normative hierarchy might possess specialised ecological or craft knowledge. The point of the diagram is therefore not to freeze people into boxes but to show how the charter assembled different groups because a grant needed their recognition or obedience. The administrative document makes society visible through its own purpose. Historians must reconstruct the wider life behind that selective visibility.

Figure 109 — A Pāla charter's social and service field

28.15 Craft labour at Mudgagiri/Munger

Recent study of Pāla sculptural material from Munger is important for labour history because unfinished sculptures preserve stages of carving and polishing. Such objects demonstrate production, not merely consumption. A finished image in a temple can travel far from its workshop; an unfinished image is stronger evidence for local or nearby working activity. Stone carving required quarry access or imported blocks, transport, specialised tools, design knowledge, roughing out, finishing and often inscription. Mudgagiri's administrative and religious importance created demand for such work. We should not assume one permanent guild or hereditary workshop without direct evidence, but the material record supports skilled śilpakāras operating within a patronage environment where court, temple and urban demand could sustain specialised production.

28.16 Antichak/Vikramaśīla and institutional demand

The excavated complex at Antichak demonstrates the labour demands of a large monastic institution. Brick architecture, drains, cells, shrines, terracotta plaques, pottery, seals and sealings, metal objects, stone

sculpture and bone, shell and ivory objects represent many kinds of work. The monastery required builders during major construction phases and continuing labour for repair, cooking, cleaning, water management, storage and provisioning. Some craft production may have occurred on site; other goods were brought through surrounding markets and villages. Archaeology cannot assign every object to a named community, but it establishes an economy of skilled and unskilled labour around the institution. Vikramaśīla was thus not only a centre of learning and ritual but also a sustained consumer of regional labour.

28.17 Potters and the archaeology of everyday production

Ceramics are among the most abundant archaeological traces of labour because vessels break and are discarded. Pottery at Antichak and other sites points to repeated production for cooking, storage, serving and ritual use. Potters needed clay, water, fuel, forming skills, firing knowledge and access to consumers. Production could be household based, village based or concentrated near larger settlements; the archaeological record rarely tells us the social identity of the potter directly. The historical importance of pottery lies precisely in its ordinariness. Monumental patronage highlights elite art, but daily institutional and household life depended on large quantities of replaceable craft goods. A social history of occupations must therefore place ordinary ceramic labour alongside prestigious stone and bronze work.

28.18 Metalworkers, repair and the economy of tools

Iron tools and fittings, copper objects and bronzes reveal different sectors of metalworking. Agricultural expansion required cutting implements, plough components, knives and repair. Buildings required clamps, hinges, nails and tools. Religious institutions demanded lamps, vessels and images. Military establishments required weapons and equipment. The same smith could serve a mixed local clientele rather than a single specialised market. Metalworking also linked workers to supply chains for ore or scrap, charcoal and fuel. Because finished metal was frequently recycled, archaeology underrepresents the scale of production. The presence of iron and copper objects at Antichak therefore signals technical labour while leaving workshop organisation open. We should distinguish evidence for metal use from evidence for a resident hereditary smith community.

28.19 Stone carvers, image makers and artistic skill

Pāla-period eastern India is famous for stone sculpture, but the social history of the people who made it is less visible than the art itself. Munger's unfinished pieces help recover sequences of manufacture, while wider eastern Indian evidence preserves occasional references to artists and engravers. By the Sena period, the Deopara inscription famously praises Śūlapāṇi as a leading figure among the artists of Varendra; whether the phrase proves a formal guild remains debated. For this volume the safer conclusion is that skilled artistic communities and reputational networks existed, with mobility between patronage centres. Stylistic similarity can suggest shared training or models, but it should not be converted automatically into a named workshop unless material or inscriptional evidence supports that step.

Occupation depended on place and demand

Village / fields	cultivation • herding • fishing • pottery • repair
Market / ferry	transport • brokerage • toll collection • food and craft exchange
Town / court	scribal work • administration • military service • luxury craft
Monastery / temple	building • image making • cooking • supply • maintenance

Figure 110 — Occupation depended on place and demand

28.20 Scribes and engravers as documentary professionals

Copper-plate grants were material products of specialised literacy. A royal decision had to be formulated in Sanskrit, copied, checked, engraved on copper and authenticated with a seal. The Bhagalpur plate names Maṅghadāsa, son of Śubhadāsa and associated with Samataṭa, as its engraver. Such notices are valuable because they reveal named technical specialists and, in some cases, geographic mobility. Sanjukta Datta's work on Pāla copper plates shows that engraving and charter production formed a documentary culture with identifiable practitioners. Scribes and engravers occupied an intermediate world between administration and craft: their work required linguistic training, graphic skill and institutional access. Their visibility contrasts sharply with the anonymity of most cultivators and manual workers.

28.21 Ritual specialists and the labour of institutions

Temples and monasteries created regular work beyond the roles of monks, teachers or Brahman recipients named in grants. Worship required flowers, lamps, food offerings, water, cleaning, music or recitation in some contexts, repair of buildings and management of supplies. The Bhagalpur grant explicitly supports worship, offerings, charitable feeding, construction and care for the sick at a Śaiva-Pāśupata establishment. These purposes imply cooks, suppliers, builders, attendants and medical provisioning even though the workers are not individually named. Institutional endowments thus transformed agricultural revenue into recurring service demand. The economic significance of religious patronage lay partly in this conversion of landed income into labour, materials and maintenance.

28.22 Merchants, brokers and market-facing occupations

Chapter 27 showed that markets linked villages, towns and institutions. Labour history adds the people who made those connections work: merchants, brokers, transporters, weighers, packers, boat operators and petty vendors. Direct evidence for each role in Mithila and Aṅga is uneven, so the Rajbhita inscription from the wider Pāla world remains a comparative control rather than a local template. It records an organised vaṇiggrāma associated with rural markets and demonstrates that commercial specialisation could develop outside large cities. Merchant organisation also created demand for credit, storage, security and information.

The boundary between occupation and social group could therefore harden through repeated cooperation and shared interests, but this was a process rather than an automatic consequence of trade.

28.23 Kaivartas and the danger of a single occupational translation

Some Pāla-period eastern Indian charters include Kaivartas in ranked social lists. The term has long associations with water, fishing, boating and later social identities, yet it should not be given one timeless occupational meaning. Riverine skills were economically important across the Ganga plain, but a label could broaden, change status or acquire political significance over centuries. The later Kaivarta mobilisation in Varendra belongs to a different regional and chronological context and cannot be used to define every earlier Kaivarta in Bihar. The historical value of the term lies in showing that groups associated in later evidence with specialised livelihoods were becoming socially legible. The exact relation between livelihood, status and heredity must be established case by case.

28.24 Meda, Andhra, Caṇḍāla and the rhetoric of social range

The Munger and Bhagalpur charter formulas extend their address lists to communities such as Meda, Andhra or Andhraka and Caṇḍāla. The phraseology communicates comprehensiveness and hierarchy: the king's order reaches from prestigious Brahmins and leading residents to socially subordinated groups. It would be hazardous to assign each label a fixed local occupation. Some may reflect ethnic, regional, occupational or status histories that had already been reinterpreted by Brahmanical classificatory language. What the formula establishes with confidence is unequal social recognition. People placed at the lower end of these lists were part of the inhabited and productive landscape even when elite texts represented them through stigma. Their inclusion in a grant notification is therefore evidence of presence and subordination, not a complete ethnography.

28.25 Women's labour and the documentary silence

Women are dramatically underrepresented in the occupational vocabulary of royal charters, yet rural and institutional economies could not function without their work. Food processing, water collection, animal care, textile production, childcare, transplanting, weeding and post-harvest tasks are among activities that comparative agrarian history consistently identifies as gendered labour, though the precise division varied by place and household. Women also appear as donors and patrons in some eastern Indian records, demonstrating that legal visibility was possible under particular conditions. The methodological rule is to avoid replacing documentary silence with invented detail while refusing to equate silence with inactivity. Where a task is necessary to a documented production process, the historian may identify the labour requirement without pretending to know the exact gender distribution in every locality.

28.26 Burdens, exactions and dependent labour

Land grants frequently describe donated property as exempt from various burdens and from the entry of certain royal personnel. The phrase *parihṛta-sarva-pīḍa*—freed from all burdens—signals that rural communities could be subject to claims beyond ordinary revenue. It does not enumerate those claims, and it should not automatically be translated as a precise system of forced labour. Elsewhere in early medieval India, *viṣṭi* is well attested, but its occurrence and meaning vary by region and period. For Pāla north Bihar the cautious conclusion is that state and service demands could impose labour-like or provisioning burdens on settlements, while the exact balance among compulsory work, supplies, cash dues and customary service

remains uncertain. Exemption formulas reveal the pressure of extraction even when they do not describe every mechanism.

28.27 From repeated livelihood to hereditary occupational group

Ryosuke Furui's regional synthesis argues that early medieval eastern India witnessed increasing organisation of hereditary occupational groups and their later systematisation within a jāti order. Figure 111 presents this as a process rather than a starting assumption. Skills can be transmitted within households because training, tools and contacts are valuable. Repeated service to the same patrons can deepen dependence. Marriage networks and normative classification can then reinforce group boundaries. Yet these stages need not occur everywhere or at the same speed. A potter family might transmit craft skills for generations without belonging to a fully closed regional caste system in an earlier century. The chronology of social closure is therefore as important as the identification of occupation itself.

From work to social group: a historical process

Figure 111 — From work to social group: a historical process

28.28 Regional variation across Mithila, Vajji and Aṅga

The three regional zones did not offer identical labour environments. North Bihar's alluvial and riverine landscape privileged cultivation, cattle, fisheries, ferries and seasonal transport, while its charter record emphasises villages and administrative units. Aṅga's Ganga corridor, Mudgagiri and the large institution at Antichak created stronger archaeological visibility for urban, artisanal and institutional labour. Older centres in the Vajji landscape continued to carry religious and route significance, but early medieval occupational documentation is thinner. These differences are partly historical and partly archival. Where inscriptions survive, officials and rural categories become visible; where excavations are rich, crafts and material work come forward. Regional comparison must therefore distinguish differences in past society from differences in what has been preserved and studied.

28.29 Methodological rules for occupational history

Six rules guide reconstruction. First, do not equate occupation, title, status and caste. Second, treat charter lists as administrative classifications, not censuses. Third, use archaeology to demonstrate production

before assigning producer identity. Fourth, distinguish necessary labour from documented labour: a monastery required cooks and cleaners even if their names are absent, but their precise organisation may remain unknown. Fifth, keep comparative eastern Indian evidence explicitly comparative unless a regional anchor exists. Sixth, date processes of heredity and jāti consolidation rather than projecting later social formations backward. These rules produce a less dramatic but more reliable account. They also recover workers as historical actors without pretending that the sources preserve their voices equally.

28.30 Conclusion: work connected the regional economy

Early medieval Mithila, Vajji and Aṅga were held together not only by kings, grants and institutions but by work. Cultivators produced the agrarian base; transport workers connected river and road; officials converted royal orders into local practice; artisans built, repaired and supplied towns and monasteries; scribes and engravers materialised documentary power; servants and military retainers sustained coercive institutions. Social hierarchy shaped who controlled resources and who remained anonymous. Over time, repeated livelihoods, household transmission, patronage and Brahmanical classification could contribute to more hereditary occupational identities, but the process was uneven. The strongest regional evidence therefore supports a differentiated labour society in motion—not a timeless caste chart. Chapter 29 turns from occupational organisation to the changing relations of household, kinship and social reproduction that sustained these communities.

Table 28.1 — Evidence for labour and occupational communities, with limits of inference

Evidence	What it shows	Historical use	Limit of inference
Bhagalpur plate of Nārāyaṇapāla	Long roster of officials and servants; residents; kṣetrakaras; ranked social range	Administrative visibility of specialised service and cultivators	Not a census; formulaic hierarchy does not define each group's occupation
Munger plate of Devapāla	Officials for tolls, policing, territorial control, movement, ferries and animals; mahattaras and kuṭumbins	Specialised state service and differentiated rural society	Titles do not reveal wages, recruitment or hereditary tenure
Grant exemption formulas	parihṛta-sarva-pīḍa and exclusion of cāṭa-bhaṭa entry	Villages could face burdens and intrusive service demands	Does not by itself prove a specific local system of viṣṭi
Antichak/Vikramaśīla archaeology	Pottery, terracotta, stone, metals, seals, architecture and drains	Large institutional demand for skilled and routine labour	Objects rarely identify the social group of the producer
Unfinished Pāla sculptures at Munger	Visible stages of carving and polishing	Local or nearby skilled stone-working activity	Does not establish one permanent guild or caste workshop
Bhagalpur named engraver Maṅghadāsa	Named specialist associated with charter manufacture	Professional literacy, engraving skill and mobility	One named artisan does not define all scribal organisation
Wider eastern Indian Kaivarta / occupational evidence	Occupational labels and later processes of group consolidation	Comparative model for increasing hereditary organisation	Cannot be projected unchanged into every locality or earlier century
Furui's regional synthesis	Stratified land relations and occupational groups increasingly systematised toward jāti	Long-term process of social differentiation	A model to test regionally, not a substitute for local evidence

Chapter 29 — Social Classification and Its Historical Formation

Social hierarchy in early medieval Mithila, Vajji and Aṅga was real, but its categories were historical rather than timeless. Land, office, ritual authority, occupation, migration, household standing and stigma generated overlapping distinctions. This chapter reconstructs how those distinctions became socially legible and, in some settings, increasingly hereditary. It refuses two opposite shortcuts: treating normative varṇa as a complete census, and projecting later caste lists backward into centuries for which they are not documented. Contemporary charters from Munger and Bhagalpur provide the principal regional anchors; wider eastern Indian evidence supplies comparison; later Maithil genealogy is used only with explicit chronological controls.

29.1 Social classification as a historical problem

Every society classifies people, but the categories used by rulers, ritual specialists, households and later ethnographers are not identical. Early medieval Mithila, Vajji and Aṅga were marked by inequalities of landholding, service, ritual prestige, occupation, dependency and political power. Some of these differences were expressed through Sanskrit terms that later became associated with caste. Others were recorded as offices, household ranks, ethnonyms or local status labels. The task is therefore not to ask when a complete modern-style caste system suddenly appeared. It is to reconstruct how social distinctions became more explicit, more hereditary in some settings, and more closely connected with marriage, land, ritual authority and occupational reproduction. This chapter treats classification as a process. It uses contemporary charters as its strongest regional evidence, normative texts as evidence for ideals, and later genealogical or caste records only after applying a strict chronological filter.

29.2 Varṇa and jāti must be kept analytically distinct

Varṇa supplied a broad normative language of ranked social order. Jāti, in historical usage, could refer to birth, kind, community or more bounded social groups, and its meanings changed across genres and periods. Treating the four-varṇa scheme as a literal census obscures the much denser social vocabulary of inscriptions. Conversely, translating every occupational or regional label as a fully formed caste imports later closure into earlier evidence. The early medieval record contains Brahmins, officials, soldiers, cultivators, rural notables, service personnel and groups placed low in Brahmanical rankings, but these categories operate at different scales. Varṇa is most useful for understanding normative ranking; jāti formation is better approached through evidence of repeated group names, marriage boundaries, inherited occupation, collective rights and durable social reproduction. Those forms do not appear at the same speed everywhere, which is why regional chronology matters.

29.3 Four evidence streams and their limits

Figure 112 separates the evidence into charters, normative texts, material history and later records. Charters are dated transactions and therefore provide the strongest control for categories made administratively visible. Normative texts tell us how learned traditions imagined social order, but prescription does not equal practice. Archaeology reveals unequal settlement, access to goods, specialised production and institutional demand, yet it rarely names the social identity of the people who made or used objects. Later genealogies, caste handbooks and colonial descriptions can document identities that had become important by their own time, but they are dangerous when projected backwards. The chapter therefore asks four

questions of every label: when is it attested, who used it, for what purpose, and what social relation does it actually demonstrate? Only after these questions are answered is comparison across periods legitimate.

29.4 The Munger plate: classification in an administrative act

Devapāla's Munger plate of year 33, issued from Mudgagiri, is unusually informative because its notification moves through a long chain of office-holders and then addresses residents through an explicitly broad social range. The charter names royal and provincial officers concerned with administration, coercion, tolls, forts, transport and animals. It then turns to local society, including Brahmins, mahattaras and kuṭumbins, and extends the formula to Medas, Andhrakas and Caṇḍālas. This is not a neutral ethnographic list. Its purpose is to announce a grant and command compliance. Yet precisely because the grant had to be socially effective, the formula shows categories that the issuing administration considered intelligible. It also shows that political authority imagined the village social field as differentiated rather than homogeneous. What remains uncertain is the population, wealth, occupation and marriage practice of each category named.

29.5 The Bhagalpur plate: hierarchy, service and local society

Nārāyaṇapāla's Bhagalpur plate of year 17, also issued from Mudgagiri and concerning a village in Tīrabhukti, repeats the broad logic while adding a rich roster of officials and servants. It addresses royal personnel, provincial and village officers, transport-related staff, cāṭas, bhaṭas and sevakas, then turns to residents extending from Brahmins through locally prominent categories to Meda, Andhra and Caṇḍāla. The same charter separately instructs resident cultivators to render the assigned revenues to the beneficiary. This produces a layered documentary picture: political office, service, local standing, cultivation and ranked social categories overlap without becoming identical. The plate is particularly valuable for Mithila because the granted village lay in Tīrabhukti. It demonstrates a classificatory language operating within the region, while leaving open how rigidly its categories structured everyday marriage and occupation.

29.6 From Brahman to Caṇḍāla: what the formula does and does not prove

The phraseology stretching from Brahmins toward groups placed at the lower end of the social scale communicates comprehensiveness and hierarchy. It tells the reader that the order binds the whole inhabited community, not only elites. It also reflects a Brahmanical vocabulary in which some groups carried stigma. But a rhetorical range is not a population table. The formula does not tell us what proportion of a village belonged to any category, whether all named groups lived in every granted settlement, or how local people described themselves. Nor does it establish a single occupational definition for Meda, Andhra or Caṇḍāla. The secure inference is narrower and more important: royal documentary practice recognised a graded social field and expected that field to be administratively intelligible. The historian must resist turning that recognition into a finished caste diagram.

29.7 Mahattara and kuṭumbin: status without automatic caste identity

Mahattara and kuṭumbin are among the most useful labels for reconstructing rural differentiation because they point toward social standing without fitting neatly into a varṇa chart. Mahattaras appear as locally important or senior persons; kuṭumbins are substantial householders in many eastern Indian inscriptions. Their authority could derive from land, household resources, participation in boundary knowledge, or local mediation. These positions could become socially reproducible, yet the terms are not equivalent to modern caste names. Their presence reminds us that hierarchy was generated not only by ritual classification but also by agrarian resources and local influence. A family controlling land, cattle, labour and

information could exercise power whether or not a surviving text gives it a fixed jāti label. Social formation therefore involved the interaction of economic position and classificatory language, not the simple application of a pre-existing fourfold schema.

29.8 Cultivator is an economic relation before it is a caste label

The Bhagalpur plate's resident kṣetrakaras matter because they were responsible for producing the revenues transferred by the grant. The word identifies cultivators more securely than it identifies a closed hereditary community. Cultivation rights could coexist with differences in tenancy, household scale, labour dependence and status. Some cultivators may have been substantial householders; others may have worked land under more dependent conditions. Over time, repeated agrarian roles could contribute to inherited social identities, but the charter itself does not prove that all cultivators belonged to one bounded caste. This distinction is essential in a region where later agrarian communities developed strong caste identities. Historical method requires starting from the relation documented in the ninth-century charter and tracing later consolidation forward, rather than using a modern agricultural caste list to interpret an earlier kṣetrakara automatically.

29.9 Offices, professions and social heredity

Administrative titles could become associated with families because literacy, court access and technical knowledge were often transmitted through households and patronage networks. Yet an office is not automatically a caste. The Pāla rosters distinguish ministers, military commanders, record-keepers, revenue and police staff, frontier officials, messengers and transport supervisors. Some of these roles may have drawn repeatedly from particular families or social networks. Others could have been appointments dependent on royal favour. The evidence is strongest when a title recurs across generations in identifiable kin groups; it is weaker when only the occupational designation survives. This is especially important for later identities connected with scribal service. The route from professional literacy to a hereditary corporate community is historically plausible, but its timing must be demonstrated. Early medieval charters reveal a specialised service world; they do not by themselves yield a complete genealogy of later service castes.

29.10 Figure 112: why a caste history needs multiple archives

Figure 112 summarises the chapter's method. A charter can show that a category mattered in an administrative transaction; a normative text can show that learned authors ranked or theorised it; archaeology can show the material inequalities within which people lived; a later genealogy can show that a corporate identity became important at a later date. The strongest historical argument arises where these streams overlap without being collapsed. If a later genealogy supplies a lineage name that never appears in earlier inscriptions, the absence matters. If a charter names a group but later records reorganise it under another label, the change matters. Caste history is therefore not the recovery of an ancient master list. It is the history of how different institutions repeatedly named, ranked, reproduced and contested social boundaries.

Social classification: distinct evidence streams

Figure 112 — Social classification: distinct evidence streams

29.11 Agrarian expansion created new contexts for ranking

Chapter 26 showed that land grants altered rights over revenue, resources and settlement. These changes also affected social classification. When new or reorganised agrarian zones were granted to religious beneficiaries, the state had to identify local authorities, cultivators and people liable to obey the transfer. Brahman settlement networks could introduce or strengthen Sanskrit status vocabularies, while local household hierarchies continued to shape actual production. This interaction could generate new forms of ranking. A community that controlled land or mediation might gain recognition; another linked to stigmatised labour could be placed lower in normative schemes. Yet agrarian expansion was not a uniform programme of caste creation. The balance among migrant beneficiaries, established residents, local elites and dependent workers differed by place. Social classification should therefore be read as one dimension of agrarian reorganisation rather than as a separate religious superstructure imposed unchanged on every village.

29.12 Brahman settlement networks and the construction of authority

Ryosuke Furui's work on early medieval Bengal emphasises that Brahman authority itself had a history. Brahmans established networks through migration, land grants, ritual expertise and ties to kingship; their clearer corporate identity was produced through these processes rather than simply present outside history. The same caution is useful for Mithila and Aṅga. Grants to Brahman or religious beneficiaries could create durable centres of learning, ritual and property management. Such centres helped circulate genealogical, gotra and normative vocabularies. But the regional record must decide when particular corporate forms became important. A ninth-century charter identifying Brahmans does not automatically prove the full institutional structure of later Maithil Brahman communities. The historical question is how authority became local, reproducible and connected with land, marriage and political patronage over successive centuries.

29.13 Political service could generate rank as well as income

Service to court and administration offered more than wages or perquisites. It created proximity to rulers, access to records, mobility and opportunities for landholding. Titles such as *rājanaka*, *amātya*, *mahāsāmanta*

or record-office positions expressed different levels of political incorporation. Families able to reproduce such service might convert office into social prestige. At the same time, service categories such as *cāṭa*, *bhaṭa* and *sevaka* could denote much more dependent relationships. The state therefore produced its own hierarchy, intersecting with ritual ranking but not reducible to it. A person of high political office could derive status from command and patronage; a Brahman beneficiary could derive status from ritual and textual authority; a substantial householder could derive it from land and local influence. Early medieval social order was formed where these sources of rank met, reinforced one another or came into tension.

29.14 Religious institutions were also social institutions

Buddhist monasteries, Śaiva establishments, temples and Brahmanical centres organised patronage, labour and access to resources. Their inscriptions classified donors, teachers, beneficiaries and service relationships in institution-specific ways. The Bhagalpur charter, for example, supports a Śaiva establishment while being issued by a Pāla ruler within a wider Buddhist political tradition. This plural institutional world complicates any notion that one religious ideology mechanically produced all social categories. Religious institutions could reinforce hierarchy through rules of eligibility and purity, but they could also create alternative networks based on monastic rank, initiation, donation or learned authority. Social classification was therefore plural. A person could simultaneously occupy a household position, occupational role, ritual category and institutional identity. Later caste boundaries sometimes gathered these dimensions together, but the earlier record often preserves them separately.

29.15 Ethnonyms and origin labels in the charter world

Pāla charters include names such as Gauḍa, Mālava, Khaśa, Hūṇa, Kaṇṇāṭa and Lāṭa among military or service personnel. These labels remind us that royal establishments were mobile and multi-regional. They should not be forced into a caste taxonomy. Some refer most naturally to geographic or ethnic origin; some may have become occupationally stereotyped in particular contexts; some could acquire new social meanings after migration. The key point is that early medieval classification included origin and political service alongside ritual status. A person's social identity could be shaped by where a group was thought to come from as well as by what it did locally. This mobility challenges models in which every community is imagined as immobile within a fixed village hierarchy. Migration was itself one of the forces through which new identities could be formed and later naturalised.

29.16 Meda, Andhra and Caṇḍāla: naming the social margins

Groups placed at the lower end of charter address formulas deserve attention because elite historiography has often rendered them invisible. Their inclusion shows that subordinated communities were part of the productive and governed landscape. Yet the labels are difficult to interpret. Andhra may function as an origin term in some contexts; Meda has different associations across texts; Caṇḍāla carries strong stigma in Brahmanical normative traditions. The charter does not provide occupational biographies. It tells us instead how the issuing authority represented the social range of its subjects. The historian should therefore recover two facts at once: real inequality and uncertain local semantics. Stigma in elite language is evidence of hierarchy, but it cannot substitute for the voices, livelihoods or self-identifications of the people named. Classification from above must be read as power, not simply description.

29.17 Untouchability requires evidence, not retrospective assumption

Brahmanical texts developed increasingly elaborate rules concerning purity, contact and groups regarded as impure. These traditions are indispensable for the history of exclusion, but a textual rule is not proof that every locality enforced the same boundary in the same way. Early medieval inscriptions can demonstrate subordinated social placement; they rarely describe the daily mechanics of avoidance, residential segregation, access to water or commensality in enough detail to reconstruct a uniform regime. Archaeology also seldom identifies caste directly. The safest conclusion is that graded notions of purity and stigma were historically powerful and that some named groups were placed at severe social disadvantage, while the exact practices of exclusion must be documented where possible. This avoids the opposite errors of denying hierarchy because evidence is incomplete and projecting a fully documented nineteenth-century untouchability regime unchanged into the ninth century.

29.18 Household reproduction made inequality durable

Classifications become socially powerful when they are reproduced through households. Land, skills, ritual knowledge, debt, patronage and social reputation can all pass between generations. Marriage links households into wider networks and can either reinforce or cross social boundaries. Early medieval charters rarely record these processes directly for ordinary residents, but the logic of household property is visible in agrarian society, while genealogical claims become increasingly important in later periods. The central point is not that every category was already endogamous. It is that household reproduction supplied a mechanism through which unequal positions could become durable. A locally powerful kuṭumbin family could transmit resources; a craft household could transmit skill; a Brahman lineage could transmit textual and ritual capital; a dependent household could inherit vulnerability. Jāti formation is best understood against this broader history of social reproduction.

29.19 Gender is part of classification even when women are unnamed

Social ranking was reproduced through marriage, inheritance, labour and ritual eligibility, all of which were gendered. Yet royal charters overwhelmingly name male office-holders and beneficiaries, making women less visible than their social importance warrants. Normative texts discuss women extensively but often from the standpoint of male household authority. The historian must therefore distinguish documented rules from actual practice. Marriage restrictions are especially important because later caste systems made endogamy central, but the date at which specific regional marriage circles hardened must be demonstrated. Women's property rights, widowhood, dowry-like transfers and household labour also varied by legal and social context. Chapter 32 examines women, marriage and property directly. Here the methodological point is narrower: any history of caste formation that ignores the gendered reproduction of households misses one of the principal mechanisms through which social boundaries became durable.

29.20 Figure 113: the charter field is not a pyramid

Figure 113 deliberately avoids drawing a caste pyramid. The Munger and Bhagalpur formulas bring together royal service, local standing and a ranked social range in the same administrative act. These domains overlap, but the charter does not tell us that every official occupied a fixed ritual rank above every cultivator, or that each named group formed a closed endogamous unit. A pyramid would therefore create more certainty than the source permits. The diagram instead represents multiple fields of classification whose members were all required to recognise the grant. This is historically significant because it shows that

hierarchy had several institutional bases. A person's position in political service, rural property, ritual status and local community could interact without being reducible to one universal scale.

A Pāla charter addresses a social field—not a census

Figure 113 — A Pāla charter addresses a social field, not a census

29.21 Markets and towns complicated village classification

Chapter 27 showed that villages, markets, ferries, towns and institutions formed connected networks. Mobility through those networks could loosen as well as reinforce social boundaries. Merchants dealt across settlements; transport workers crossed jurisdictions; artisans served patrons beyond one village; officials moved with courts and camps; students and monks travelled among religious centres. Such mobility created opportunities for new associations based on profession, patronage and commercial interest. It also created situations in which outsiders had to be classified. Market society therefore did not abolish hierarchy; it produced additional contexts in which social reputation and group identity mattered. The relation between caste and commerce was dynamic. Some occupational communities could become more corporate through repeated exchange networks, while individual mobility could challenge a purely local hierarchy. Early medieval social formation must accommodate both tendencies.

29.22 Mudgagiri and Aṅga: a politically cosmopolitan social setting

Mudgagiri's repeated role as a Pāla jayaskandhāvāra and the large administrative rosters issued from it make the Aṅga–Munger zone especially important for the study of classification. Court, army, transport and documentation brought together people of different geographic origins and service positions. The Munger plate's list of Gauḍa, Mālava, Khaśa, Hūṇa, Kulika, Karṇāṭa and Lāṭa personnel is evidence for this cosmopolitan political environment, regardless of the precise status of each label. Such a setting could generate new dependencies and reputations. It also demonstrates why later caste geography cannot be imagined as a collection of isolated villages. State centres connected local society to wider circuits of recruitment and migration. Aṅga's social history therefore includes both rooted agrarian communities and mobile political-service populations, whose classifications operated on different principles.

29.23 Mithila and the problem of uneven evidence

Tīrabhukti appears in the Bhagalpur charter, giving a direct regional anchor for the ninth century, but the surviving social documentation for Mithila is not as continuous as historians might wish. Later medieval records are much richer for Brahman genealogies, court culture and marriage regulation. The temptation is to bridge the documentary gap by treating later institutions as survivals from remote antiquity. This chapter rejects that method. Where a ninth-century charter names a category, it may be used for the ninth century. Where a fourteenth-century or nineteenth-century source describes a ranked community, it must first be used for its own period. Continuity can then be argued only if intermediate evidence supports it. This chronological discipline is especially important in Mithila, where powerful later traditions of genealogy can easily create the illusion that every later social distinction was already fully formed under the Pālas.

29.24 Regional identity and caste identity are different things

Labels such as Maithila, Gauḍa or Kaṇṇāṭa can refer to regions, cultural affiliations, scholarly identities or political origins, depending on context. A regional adjective may later become attached to a caste community, but the two categories should not be conflated from the start. Migration can convert regional origin into a durable social marker, especially when newcomers reproduce marriage networks and institutions. Conversely, people of different social ranks can share the same regional identity. The emergence of a specifically Maithil Brahman identity in later medieval evidence is therefore a historical development involving territory, genealogy and authority, not proof that every Brahman in ancient Videha belonged to the later corporate community. The same rule applies elsewhere: geography can contribute to social identity, but regional belonging does not by itself establish caste boundaries.

29.25 Brahmanisation and Sanskritisation are processes, not a one-way map

Historians often use terms such as Brahmanisation or Sanskritisation to describe the spread of Brahmanical institutions, practices and status vocabularies. These concepts are useful only if they preserve negotiation. Local rulers sought ritual legitimisation; Brahmins depended on patronage and agrarian support; communities could adopt, reinterpret or resist ranked categories; religious traditions competed and overlapped. Classification therefore emerged through interaction rather than one-sided cultural replacement. A local group might seek higher status by changing ritual practice or genealogy, while elites could redefine local identities within textual schemes. Such processes also produced exclusions. The result was neither total fluidity nor a single unchanged code. It was a historically changing field in which social actors used available languages of rank to secure resources, honour and marriage alliances.

29.26 Mobility, claim-making and the negotiation of rank

Hereditary classification does not eliminate social mobility; it changes the forms through which mobility is pursued. Families can seek new titles, land, patronage, ritual recognition or genealogical narratives. Political upheaval can elevate military or administrative groups; migration can detach a community from an older rank; wealth can support new claims; defeat or dependency can lower status. Early medieval inscriptions preserve some of these processes indirectly through the appearance of new local magnates, subordinate rulers and beneficiaries. Later genealogies often naturalise the achieved position by projecting it backward. A historical approach therefore reads status claims critically. The question is not whether a community's tradition is "true" or "false" in a simple sense, but when a claim appears, what institutions recognised it, and what social interests it served. Rank was real precisely because it had to be repeatedly reproduced and acknowledged.

From social role to more bounded identity: possible pathways

Figure 114 — From social role to more bounded identity: possible pathways

29.27 Dharmashāstra ideal and inscriptional practice

Dharmashāstra literature provides an elaborate language of varṇa, mixed descent, occupation, inheritance and purity. It shaped elite ideas and legal reasoning, but inscriptions show a social world with categories that do not fit neatly into four boxes. The Pāla charters are crowded with offices, household ranks, service groups and regional names. This discrepancy is not evidence that normative texts were irrelevant; rather, it shows that norms worked on a complex social field. Learned authors could reinterpret occupational or regional groups within varṇa-based schemes, while political documents continued to use categories required by administration. The history of caste formation lies partly in the growing effort to connect these two worlds: to systematise diverse social groups through Brahmanical classification while those groups retained distinct economic and regional histories.

29.28 Why later caste lists cannot be projected backward

Late precolonial and colonial observers often present social groups as if each possessed an ancient, bounded and universally recognised place. Such lists are valuable evidence for the period in which they were compiled, but they are not keys that decode every earlier inscription. A modern caste name may descend from an older occupational term, absorb several earlier groups, split from a broader community, or acquire a new ranked meaning. Figure 115 therefore applies a time-depth filter. Contemporary inscriptions receive the greatest weight for their period; near-contemporary normative texts require genre analysis; later genealogies are evidence for later corporate formation; colonial surveys are late snapshots. Backward projection erases change, which is precisely the phenomenon the historian is trying to explain.

Time-depth filter for using social labels

Contemporary inscription	Highest control	What did this administration actually name?
Near-contemporary text	Context required	Ideal, polemic, narrative or social observation?
Later genealogy / ritual record	Retrospective evidence	Useful for later formation; not automatic proof of earlier existence
Colonial / modern caste account	Late snapshot	Do not project its categories unchanged into the medieval past

Figure 115 — Time-depth filter for using social labels

29.29 A specific Mithila caution: do not medievalise later Brahman sub-castes

Mithila's later Brahman genealogical system is unusually rich, but its richness makes chronological caution more necessary, not less. Later ranked labels within Maithil Brahman society must not be inserted into the Pāla or early medieval record unless contemporary evidence supports them. In particular, this volume does not treat Śrottriya as a fixed Maithil Brahman sub-caste in the medieval period. The project's Panji-based chronology places the emergence of Śrottriya as a distinct sub-caste around 1800 CE; earlier uses of śrottriya in Sanskrit can denote Vedic learning or qualification and are not the same corporate category. Chapter 30 examines Brahmanical institutions without retrospective caste projection, and Chapter 31 treats the Panji tradition directly. The present chapter therefore establishes the governing rule: later internal rankings belong first to the period in which they are actually evidenced.

29.30 Conclusion: classification was made, reproduced and revised

The strongest evidence from Mithila, Vajji and Aṅga does not support either a timeless caste order or a society without hierarchy. Pāla charters reveal graded social language, powerful Brahmans, local notables, cultivators, specialised service populations, mobile origin groups and communities placed at the social margins. Agrarian expansion, political office, institutional patronage, household reproduction and normative classification could make some identities more hereditary and more bounded over time. Yet the process was uneven, and later genealogies reorganised earlier social memories. Social classification must therefore be written as history: categories were made visible by institutions, reproduced through resources and marriage, contested by mobility and claim-making, and repeatedly reinterpreted. Chapter 30 now turns specifically to Brahmanical institutions, applying this same chronological discipline so that later Maithil caste structures are not projected backward into periods that did not yet possess them.

Table 29.1 — Evidence for social classification and limits of inference

Evidence	Category / content	Historical use	Limit of inference
----------	--------------------	----------------	--------------------

Evidence	Category / content	Historical use	Limit of inference
Munger plate of Devapāla	Officials; Brahmins; mahattaras; kuṭumbins; Meda, Andhraka and Caṇḍāla range	Administrative recognition of differentiated and ranked society	Not a census or complete map of marriage and occupation
Bhagalpur plate of Nārāyaṇapāla	Royal personnel, service groups, residents and cultivators in Tirabhukti	Direct Mithila-region evidence for layered classification	Formulaic address does not prove fixed hereditary closure
Mahattara / kuṭumbin	Local seniority and substantial household standing	Rural hierarchy outside a simple four-varṇa chart	Should not be translated as modern caste names
Kṣetrakara	Resident cultivator liable to deliver assigned revenue	Agrarian role and fiscal relationship	Occupation does not automatically equal caste
Origin / military labels	Gauḍa, Mālava, Khaśa, Hūṇa, Karṇāṭa, Lāṭa and others	Mobility and multi-regional recruitment	Geographic or service labels are not inherently jātis
Dharmashāstra and Purāṇic classification	Varṇa, purity and mixed-category models	Normative language influencing social ranking	Prescription and polemic are not demographic description
Early medieval eastern Indian comparison	Increasing organisation of landholding and occupational groups	Model for gradual systematisation toward jāti	Must be tested against Mithila–Anga evidence rather than imported wholesale
Later Maithil genealogy and caste accounts	Corporate identities, marriage regulation and ranked internal categories	Essential evidence for later formation	Cannot be projected backward without intermediate evidence

Chapter 30 — Brahmanical Institutions without Retrospective Caste Projection

This chapter reconstructs Brahmanical institutions in medieval Mithila, Vajji and Aṅga through land grants, learned credentials, ritual and juristic expertise, household transmission, migration and patronage. Its governing method is chronological: early-medieval Brahman identities are described in the categories actually attested in their sources, while the later corporate organisation of Maithil Brahmins is reserved for the evidence that documents it. In particular, the Sanskrit qualification śrōtriya is not treated as proof of the later Mithila Śrōtriya sub-caste.

30.1 Institution before caste category

Brahmanical power in medieval Mithila, Vajji and Aṅga cannot be reconstructed by taking a later caste list and moving it backward in time. The early and early-medieval evidence shows institutions: learned households, ritual specialists, teachers, juristic authorities, land grantees, advisers and networks of patronage. These institutions could generate durable status and reproduce privilege across generations, but their documentary form is not identical to the later corporate organisation of Maithil Brahmins. The first task is therefore to identify what an inscription or text actually makes visible. A grant may identify a beneficiary by gotra, pravara, Vedic affiliation and learning; a legal text may define an ideal qualification; a later genealogy may regulate marriage. Each belongs to a different institutional layer. This chapter reconstructs those layers without assuming that they had already fused into the later caste structure.

30.2 What counts as a Brahmanical institution

Institution is used here in a broad but concrete sense: a durable arrangement that organises knowledge, ritual, property, authority or social reproduction. A Brahmanical institution may therefore be a household maintaining a textual tradition, a grant supporting a learned beneficiary, a court using Brahman advisers, a ritual relationship between patron and officiant, or a network that connects teachers and pupils across regions. Temples and endowed settlements could also create institutional roles, but they should not be assumed wherever a Brahman is named. The advantage of this approach is that it shifts attention away from abstract status alone. Prestige became historically effective when it was attached to resources, recognised expertise, students, patrons, land, legal competence or ritual demand. These arrangements can be studied directly even where later sub-caste boundaries are absent from the record.

30.3 Four evidence streams and a chronology firewall

Figure 116 separates charters, learned texts, settlement history and later genealogy. Contemporary charters are the strongest evidence for named beneficiaries, rights and administrative recognition. Learned texts reveal the categories through which ritual and legal authority were theorised, but they do not by themselves prove local implementation. Settlement evidence helps reconstruct the material basis of learned households and religious institutions. Later genealogies are indispensable for later Maithil Brahman organisation, yet they must first be read for the period in which their regulatory machinery can be demonstrated. The governing rule is simple: no later label is allowed to migrate backward unless intermediate evidence supports continuity. This chronological firewall is especially important in Mithila because the later genealogical record is so rich that it can create the illusion of timelessness.

Brahmanical institutions: evidence before caste projection

Figure 116 — Brahmanical institutions: evidence before caste projection

30.4 Land grants as institutional documents

Copper-plate grants were not merely transfers of soil. They were instruments that redirected revenue, defined boundaries, publicised authority and established the standing of beneficiaries. When a Brahman received a village or a share of land, the document commonly identified him through learned and genealogical credentials. The grant thus connected royal or elite patronage to a household capable of claiming recognised ritual or scholarly status. Such documents also affected cultivators and local officials because fiscal obligations might be reassigned. Their institutional significance lies in this bundle: property, documentary recognition, social authority and a durable relationship to place. Yet a grant to one Brahman does not prove that every Brahman was a landholder, nor does a cluster of grants demonstrate that an entire region was socially controlled by one homogeneous Brahman corporate body.

30.5 Gotra and pravara as credentials, not later sub-castes

Gotra and pravara are recurring elements in Brahman genealogical and ritual self-description. In inscriptions they can establish lineage eligibility and make a beneficiary legible within a learned Brahmanical framework. Their presence is historically important because it shows that descent and ritual ancestry mattered to recognition. But gotra and pravara should not be converted into later sub-caste categories. Multiple later communities could contain persons of the same gotra, while marriage rules and corporate rankings developed through additional institutions. The epigraphic formula therefore documents one kind of genealogical credential, not the complete social architecture of a later caste. The distinction matters for Mithila, where later Panji records would make genealogy central to marriage regulation. Early-medieval lineage description and later genealogical administration are connected problems, but they are not the same institution.

30.6 Vedic affiliation and textual specialisation

Early-medieval charters often identify Brahman beneficiaries by Vedic school or textual affiliation. Such description points toward institutionalised learning: a person was not merely called Brahman but was located within a tradition of recitation, study and ritual competence. The Nandapur transaction discussed in

Chapter 26, for example, associates a proposed donation with a Sāmavedic Brahman and the performance of the five great sacrifices. The Bangaon record from north Bihar similarly preserves detailed learned credentials for its grantee. These references show that Vedic affiliation could be socially valuable and materially supported. They do not, however, prove the existence of a single territorially bounded Vedic corporation. Textual affiliations could travel with scholars, and learned mobility was one mechanism by which Brahmanical institutions expanded across eastern India.

30.7 Śrottriya: qualification is not the later Mithila sub-caste

The Sanskrit term śrottriya has a long history in normative and legal literature, commonly referring to a Brahman distinguished by Vedic learning or recognised qualification. That semantic history must be separated from the later Maithil Brahman sub-caste called Śrottriya. In this volume the two are never treated as interchangeable. A medieval text praising a śrottriya does not by itself attest the later corporate sub-caste. The project's Panji-based chronology places the emergence of Śrottriya as a distinct Maithil Brahman sub-caste around 1800 CE. Figure 119 makes this chronological firewall explicit. Earlier evidence may illuminate the prestige of Vedic learning; it cannot be used as proof that the later ranked sub-caste already existed. This distinction is fundamental to avoiding retrospective caste projection.

30.8 Devapāla's Munger grant: patronage from an Aṅga-region court

Devapāla's Munger plate, issued from Mudgagiri in regnal year 33, provides a strong Aṅga-region anchor for Brahmanical patronage. As discussed earlier, it records the grant of the village Meśikā in Kṛmilā-ṣaya to a Brahman beneficiary. The important historical point is not simply that a king gave land to a Brahman. The charter embeds the act in a dense administrative world of officials, residents, boundaries, revenue and royal command. Brahmanical privilege therefore operated through state documentation and agrarian institutions. Mudgagiri's position as a Pāla political centre also reminds us that the place of issue, the location of the donated property and the beneficiary's own networks could differ. Brahmanical institutions were connected through royal mobility and documentary circuits, not confined to one village or one modern region.

30.9 The Bangaon grantee: learning made visible

The Bangaon copper plate of Vigrahapāla III is especially valuable because its beneficiary, Ghaṇṭukaśarman, is described through gotra, pravara, Vedic affiliation and accomplishments in Mīmāṃsā, grammar and reasoning. These details are not ornamental. They explain why the recipient could be presented as a worthy beneficiary and show that intellectual reputation had material consequences. The charter also associates his family with migration from Kolāṅca and residence at Iṭṭāhaka, linking learning with mobility. A grant could therefore consolidate a learned household in a new locality while preserving a memory of origin. This is an institutional history of scholarship, patronage and settlement. It is not yet the later Panji system, and it does not justify assigning Ghaṇṭukaśarman to a later Maithil Brahman sub-caste.

How an early-medieval Brahman grantee was credentialed

Figure 117 — How an early-medieval Brahman grantee was credentialed

30.10 Mīmāṃsā, grammar and reasoning as social capital

The learned disciplines named in early-medieval records illuminate how Brahmanical authority could be reproduced. Mīmāṃsā trained specialists in the interpretation of Vedic injunction and ritual obligation. Grammar disciplined textual competence and linguistic analysis. Reasoning supplied techniques for argument, classification and adjudication. These were not merely abstract intellectual accomplishments: they could support teaching, ritual expertise, debate, legal interpretation and courtly service. The Bargaon record is therefore significant because it makes a cluster of scholarly qualifications visible within a land-grant context. Yet the institutional implications must be stated carefully. One learned grantee does not prove a formal college at the site. The secure inference is a recognised scholarly profile embedded in networks of patronage and household reproduction.

30.11 The Bhagalpur plate: Brahmins inside a wider social order

Nārāyaṇapāla's Bhagalpur plate is useful for a different reason. Its long notification formula addresses an administratively differentiated population that includes Brahmins but also officers, local notables, cultivators, service groups and communities placed low in elite social ranking. Brahmins therefore appear within a wider governed landscape rather than outside it. Their privilege must be analysed in relation to other social positions and to the fiscal consequences of the grant. This prevents an elite-source bias from turning Brahmanical history into the whole of social history. The same charter that recognises learned or ritual prestige also demonstrates that rural life depended on cultivators, transport, policing, service and subordinated labour. Brahmanical institutions were powerful because they were embedded in these wider social and economic relations.

30.12 Bagaha and the plurality of patrons

The Bagaha charters of Saurāditya show that Brahmanical patronage in the wider Tirabhukti sphere was not monopolised by the Pāla court. A local ruling house could issue grants to Brahmin beneficiaries and participate in the same documentary culture of merit, authority and landed endowment. This matters because institutional expansion was polycentric. Kings, subordinate rulers, ministers and local magnates

could all become patrons. The resulting network was therefore not a single centrally administered Brahmanical organisation. It was a field of relationships in which donors sought legitimacy or merit and learned households gained resources and territorial anchorage. Such plurality also helps explain variation: different localities could support different lineages, textual affiliations and ritual specialists without belonging to a single uniform corporate caste system.

30.13 Śāsana, agrahāra and the problem of settlement labels

Terms such as śāsana and agrahāra are often used for endowed settlements or privileged holdings associated with Brahman beneficiaries, but their meanings vary across inscriptions and regions. Historians should therefore avoid treating every Brahman grant as proof of an identical settlement form. What can be reconstructed more securely are specific rights: fiscal exemptions, revenue assignment, boundary recognition, policing privileges, pasture, water, trees or uncultivated land. These rights could strengthen a learned household and reshape its relation to cultivators and local officials. A settlement might become a node of teaching and ritual, but the institutional content must be demonstrated rather than assumed from the label alone. This source discipline prevents a useful technical term from becoming an all-purpose explanation for Brahmanisation.

30.14 Teaching without inventing a university

Brahmanical learning was reproduced through teachers, pupils, households and itinerant scholars. The evidence rarely allows the historian to map these relations as a modern school system. A grantee described as learned in several disciplines may have taught; a respected household may have attracted pupils; court centres may have concentrated intellectual exchange. But unless a source explicitly identifies a teaching establishment, the safest language is network, household, circle or lineage of learning rather than university. The regional history developed in Chapters 17 and 27 already showed that intellectual life could be highly organised without taking the form of a single campus institution. Brahmanical scholarship should be reconstructed with the same restraint. Its durability lay in repeated transmission, not necessarily monumental educational architecture.

30.15 Ritual service and the political economy of merit

Brahmanical institutions drew resources partly because ritual service converted wealth into religious merit and political legitimacy. Donors could support Vedic rites, daily obligations, commemorative acts or learned beneficiaries whose status made the gift meritorious. The economic history is therefore inseparable from a ritual economy: land and revenue could sustain persons whose expertise was represented as spiritually and socially valuable. This relationship was reciprocal but unequal. Patrons gained legitimation; beneficiaries gained resources and recognition; cultivators might experience a redirection of dues without sharing equally in the resulting prestige. The system should not be romanticised as pure patronage. It was a mechanism by which symbolic authority and material resources reinforced one another.

30.16 Dharmaśāstra and juristic expertise

Brahmanical legal literature provided vocabularies for property, inheritance, ritual status, penance, marriage and royal duty. Its historical force depended on specialists who interpreted and applied these traditions in particular settings. A text such as the Yājñiavalkya Smṛti became especially important in later legal commentary, but the existence of a textual tradition does not mean that every rule governed every village exactly as written. Juristic expertise is best treated as an institutional resource: learned specialists could advise

rulers, resolve disputes, interpret donations or frame social claims. The social history of law therefore requires both texts and evidence of use. This distinction becomes crucial for Mithila, where later scholastic traditions would acquire enormous prestige. Their later density must not be projected unchanged into the Pāla centuries.

30.17 Court and Brahman: alliance without identity

Brahmanical institutions often depended on courts, yet Brahmins and rulers occupied distinct roles. Royal charters praise kings as protectors of dharma and donors to learned beneficiaries, while Brahman specialists could furnish ritual sanction, textual knowledge or legal expertise. This relationship should not be reduced to a simple theory of priests controlling kings, nor to rulers mechanically using religion. Patronage was negotiated. Kings distributed resources but required networks capable of giving those acts moral and cultural meaning. Learned beneficiaries depended on political power for documentary protection yet could possess forms of authority not reducible to office. The tension between royal and Brahman authority remained productive precisely because the two were related but not identical institutions.

30.18 Landed privilege and its limits

Land grants demonstrate that some Brahman beneficiaries acquired substantial rights, but they do not prove equal wealth among all Brahmins. A learned grantee with revenue claims and a village share occupied a very different material position from a landless ritual specialist or itinerant student. Even within endowed households, resources could fragment across generations. Brahmanical history therefore requires attention to class as well as ritual rank. The documentary visibility of wealthy beneficiaries creates a strong survival bias: copper plates preserve successful grants more readily than the lives of ordinary or unsuccessful specialists. Recognising this bias prevents the category Brahman from becoming a false economic unit. Ritual prestige could coexist with varied material circumstances.

Land, learning and authority: an institutional cycle

Figure 118 — Land, learning and authority: an institutional cycle

30.19 Migration and the formation of learned networks

The origin clauses of some charters show that learned households could move across regions. The Bangaon grantee's remembered association with Kolāñca is one example of how migration could be built

into Brahman self-representation. Such movement helps explain the spread of textual traditions without requiring a single expansion from one centre. Scholars could travel to courts, settle on granted land, marry within suitable networks, attract pupils and preserve memories of origin. Over generations, migration could become territorial identity. This process is important for the later emergence of specifically Maithil Brahman corporate identity, but the two stages should not be collapsed. A mobile learned household in the eleventh century is not automatically evidence for the later bounded community regulated by Panji genealogy.

30.20 Regional identity and the later category Maithil Brahman

Maithila is an old regional name, but a regional adjective and a corporate caste identity are not the same historical object. Brahmins living in or connected with Mithila in an early period need not already have belonged to the later community defined through shared genealogy and marriage regulation. Anshuman Pandey's reconstruction emphasises the medieval formation of a specifically Maithil Brahman identity through territory, genealogy and authority, especially as Panji regulation became central. This later development should be treated as a transformation of institutions, not as proof that the same corporate body existed unchanged from ancient Videha. Regional residence, learned migration and court patronage provided ingredients; the later corporate identity required additional mechanisms of enumeration, genealogy and endogamy.

30.21 Temple institutions and source restraint

Brahmins could serve temples as ritual specialists, recipients of endowments, administrators or learned personnel, and temple economies became important in many parts of early medieval India. For Mithila and Aṅga, however, the density of surviving temple records varies sharply by place and period. The historian should therefore resist filling documentary gaps with models borrowed wholesale from better-documented regions. Where inscriptions, sculpture or architectural remains show a cultic centre, Brahmanical institutional roles may be investigated. Where such evidence is absent, it is safer to speak of possible rather than demonstrated temple organisation. This caution does not minimise religious life; it protects regional specificity and prevents southern or western Indian temple models from being imposed on eastern India without evidence.

30.22 Learned households as institutions of reproduction

The household was one of the most durable vehicles through which Brahmanical knowledge could be reproduced. Texts, ritual manuals, reputation, property and relationships with patrons could pass between generations. Sons are more visible in many elite genealogies, but the household economy also depended on women's labour, marriage alliances and property arrangements. The learned household therefore joined intellectual and domestic history. It could preserve a Vedic affiliation while adapting to new patrons and places. Yet household continuity should not be mistaken for automatic caste closure. Hereditary learning can exist before a later corporate marriage system is fully documented. The Panji tradition examined in Chapter 31 represents a more explicit institutionalisation of genealogical regulation.

30.23 Women, marriage and the invisible infrastructure of learned status

Epigraphic descriptions of Brahman grantees overwhelmingly foreground male beneficiaries, teachers and ancestors. This creates a documentary imbalance. Learned status nevertheless depended on households whose continuity required marriage, inheritance, domestic labour and the reproduction of ritual routines. Women could also appear as donors or members of elite religious networks in broader South Asian evidence,

though the regional record for this specific chapter is thinner. The methodological lesson is to distinguish absence from insignificance. Male-centred charters tell us who was legally foregrounded in a transaction; they do not provide a complete account of the social labour sustaining the beneficiary household. Chapter 32 examines women, marriage and property directly, using sources better suited to that question.

30.24 Interaction with Buddhist and Jain institutions

Brahmanical institutions did not develop in an empty religious landscape. Chapters 16, 20 and 21 showed that Buddhist and Jain communities also depended on patrons, teachers, property, itinerancy and rules for institutional reproduction. Competition and coexistence could occur within the same political region. A ruler might support different religious establishments; merchants and householders could patronise more than one tradition; scholars could debate rival systems. This plural institutional field is especially important in eastern India, where Pāla political history is closely associated with major Buddhist monasteries even while Brahman land grants continued. The coexistence of these forms warns against describing the region as moving through neatly separated religious ages.

30.25 Local negotiation beneath the royal charter

A royal grant could command, but implementation depended on local society. Boundaries had to be known, cultivators had to redirect dues, officials had to recognise exemptions and neighbouring communities had to accept the beneficiary's rights. Brahmanical privilege was therefore negotiated on the ground even when expressed in authoritative royal language. Conflict is often under-recorded because surviving charters preserve the successful legal form rather than every dispute. The institutional historian should read formulaic commands for the social work they imply. A grant required cooperation, enforcement and memory. Brahmanical institutions became durable not simply because kings issued copper plates, but because local relations reproduced the rights those plates claimed to establish.

30.26 Brahmanisation as negotiation, not replacement

The term Brahmanisation can describe the spread of Brahmanical ritual, textual authority and social categories, but it becomes misleading if imagined as the replacement of passive local cultures. Patrons selected specialists for political reasons; Brahmins adapted to regional cults and economies; local elites could seek new genealogies or ritual forms; competing religious institutions remained active. Institutional expansion was therefore negotiated. Land grants could create new centres of learned authority while existing communities continued their own practices. This negotiated model also explains diversity within Brahmanical life itself. Different households emphasised different textual affiliations, patrons and forms of service. The result was a changing field of institutions rather than a single programme imposed uniformly across Mithila, Vajji and Anga.

30.27 Hierarchy, exclusion and the costs of privilege

Brahmanical institutional history must include the inequalities that made privilege meaningful. Normative traditions ranked social groups; grants could redirect revenue to privileged beneficiaries; purity rules could stigmatise others; access to literacy and court patronage was uneven. The Bhagalpur and Munger notification formulas remind us that Brahmins existed alongside communities placed far lower in elite social language. Yet the exact local mechanics of exclusion cannot be reconstructed from formula alone. The responsible conclusion is double: Brahmanical institutions participated in real structures of hierarchy, but their effects varied by place and must be demonstrated through specific evidence. Avoiding retrospective

caste projection is not a way of softening inequality; it is a way of describing the historically correct form that inequality took.

30.28 From learned status to corporate regulation

Across the medieval period, several mechanisms could make Brahman identity more corporate: repeated grants to particular lineages, territorial settlement, hereditary learning, marriage networks, court recognition and genealogical memory. These processes help explain how a broadly Brahmanical learned status could become increasingly tied to specific regional communities. But the sequence was neither automatic nor complete at one date. Figure 118 therefore presents a cycle of patronage, learning, public function and reproduction rather than a deterministic ladder. The later Panji system added a qualitatively stronger mechanism by recording genealogy and regulating marriage. It is at that point that corporate identity becomes much more visible in Mithila's documentation.

30.29 The bridge to the Panji tradition

This chapter stops at the threshold of the Panji system because genealogy changes the evidentiary problem. Early charters identify beneficiaries through lineage and learning; later Panji records organise a much broader field of descent, village origin, marriage eligibility and internal ranking. Pandey's study reconstructs the emergence of corporate Maithil Brahman identity through this convergence of genealogy, territory and authority in the later medieval period. The next chapter will examine those records directly, including their manuscript history and chronological layers. The transition should not be described as the sudden invention of Brahman identity. Rather, older institutions of lineage, learning and patronage were reorganised within a new apparatus of genealogical regulation.

Chronology firewall: do not collapse different institutions

Figure 119 — Chronology firewall: do not collapse different institutions

30.30 Conclusion: institutions first, caste categories later

The Brahmanical history of Mithila, Vajji and Aṅga is best reconstructed through institutions before caste labels. Pāla and related charters document learned beneficiaries, gotra and pravara, Vedic affiliation, migration, land rights and relations with courts and cultivators. Learned texts illuminate ritual and juristic ideals. Households and patronage networks explain how knowledge and privilege could endure. None of this

requires the retroactive insertion of later Maithil Brahman sub-castes into the early-medieval record. The later Panji regime represents another historical stage, and the distinct Śrottriya sub-caste belongs later still in the Panji-based chronology, around 1800 CE. By keeping these layers separate, the region's Brahmanical history becomes more, not less, intelligible: institutions can be seen forming, reproducing and changing through time.

Table 30.1 — Brahmanical institutions: evidence, secure inference and chronological limit

Evidence	What it records	Secure historical inference	Chronological limit
Munger plate of Devapāla	Brahman beneficiary within a documented land grant	Royal patronage linked learned status to agrarian rights	Does not describe all Brahmans or later Maithil sub-castes
Bangaon plate of Vighrahapāla III	Gotra, pravara, Vedic affiliation and learning of Ghaṇṭūkaśarman	Detailed credentialing of a learned household in north Bihar	Not evidence for a formal university or later Panji ranking
Bhagalpur plate of Nārāyaṇapāla	Brahmans named within a much wider social and administrative field	Brahman privilege was embedded in agrarian society	Notification formula is not a caste census
Bagaha charters of Saurāditya	Local ruler grants to Brahman beneficiary in the Tirabhukti sphere	Plural patrons supported Brahmanical institutions	Does not imply one centrally controlled Brahman corporation
Gotra / pravara	Lineage and ritual ancestry	Credential for recognition and marriage-related identity	Not equivalent to a later sub-caste
Vedic śākhā / śrottriya qualification	Textual learning and recognised competence	Prestige of Vedic study	Do not equate śrottriya with later Mithila Śrottriya sub-caste
Dharmashāstra and scholastic texts	Norms of ritual, property, law and status	Languages of juristic and ritual authority	Prescription is not proof of uniform local practice
Panji tradition	Genealogy, territory, marriage regulation and later internal ranking	Documents a different phase of corporate Maithil Brahman organisation	Must not be retrojected into Pāla-era charters

Chapter 31 — The Panji Tradition

The Panji tradition transformed genealogy into an institution of social memory, territorial identity and marriage regulation in Mithila. This chapter treats the Panji neither as an timeless survival nor as a single document created once and thereafter unchanged. It reconstructs a layered archive: a fourteenth-century process of formalisation associated with the Tirhut court; genealogical and territorial categories elaborated through repeated copying; professional interpretation by Panjikars; later rank vocabularies and marriage procedures; and modern preservation, digitisation and search. The method is chronological and source-critical. Surviving manuscripts, later copies, ethnographic descriptions and modern digital collections are used together but never collapsed into one evidentiary moment.

31.1 Genealogy becomes an institution

Genealogy exists in many societies as remembered descent, but the Panji tradition is historically distinctive because descent became a maintained documentary system tied to social decisions. A lineage statement could identify ancestors; a Panji institution could preserve, compare and adjudicate relationships across households. That difference matters. The emergence of a corporate genealogical archive created new forms of expertise, because only persons who knew how to read the record, reconcile variant pedigrees and connect family histories could make the archive socially effective. It also created new forms of dependence on writing. Memory did not disappear, but written pedigrees increasingly structured how memory was verified. The Panji therefore belongs simultaneously to the history of manuscripts, marriage, professional knowledge, territorial identity and social classification.

31.2 What “Panji” means historically

In this chapter Panji refers to the formalised genealogical records and the institutional practices surrounding them, not merely to any family tree. Scholarly descriptions of Pañjī-Prabandha emphasise its role in maintaining ancestry, lineage affiliation and eligibility for marriage within recognised communities. The corpus is internally diverse. Different Panjikars possessed different manuscript sets; later copies could incorporate earlier material; and a pedigree might be transmitted through a succession of exemplars rather than preserved in the hand of its first recorder. Consequently, a statement found in a nineteenth-century manuscript may preserve older genealogical information without making the manuscript itself medieval. Source criticism must therefore distinguish the date claimed for an event, the date of the textual layer, and the physical date of the surviving copy.

31.3 Four evidence streams and a chronology firewall

The Panji cannot be reconstructed from one evidence stream alone. Surviving genealogical manuscripts provide names, relations, mūla traditions and marriage information; political history supplies the setting in which formal regulation became possible; ethnography records Panjika practice and marriage procedures in the nineteenth and twentieth centuries; and modern digital projects preserve images and searchable representations of fragile records. Each stream answers different questions. The strongest reconstruction emerges where two or more streams converge. A later ethnographic custom cannot automatically be assigned to the fourteenth century, and a traditional foundation story cannot substitute for a dated manuscript. The chronology firewall used throughout this volume is especially important here because the Panji system itself was a mechanism through which later social categories were created and stabilised.

Figure 120 — Panji history requires layered evidence

31.4 Harisimhadeva and fourteenth-century formalisation

Modern scholarship commonly places the formalisation of the Pañji-Prabandha in the fourteenth century and associates it with the Karnata ruler Harisimhadeva of Tirhut. Anshuman Pandey reconstructs this transformation as a state-backed attempt to enumerate Brahmans and organise a corporate Maithil identity through genealogy, territory and authority. Nisha Thakur likewise treats the fourteenth-century Pañji-Prabandha as a major institutional turning point. The safest historical formulation is therefore not that every extant Panji was literally written in a single founding year, but that the fourteenth century saw a decisive formalisation of genealogical regulation under royal authority. The distinction protects the history from a false precision that the surviving manuscript record cannot sustain.

31.5 Enumeration, recognition and corporate identity

A genealogical census or registration system does more than count people. It decides what information makes a person recognisable to an institution. In the Panji tradition, ancestry, lineage and territorial origin became criteria through which membership could be represented and compared. This process helped convert dispersed learned and landholding households into a more explicitly corporate community. The effect was recursive: once the archive defined legitimate relationships, subsequent marriages and claims were interpreted through the archive, which in turn accumulated new information. Genealogy thus became both record and rule. It did not erase local identities, but it created a translocal framework in which families from different villages could locate themselves within a shared documentary order.

31.6 The Panjikar as archivist, interpreter and registrar

The Panjikar was not simply a copyist. The office required command of pedigree relationships, manuscript conventions and the practical rules by which genealogical distance was judged. Ugra Nath Jha's study of Panji and Panjikars shows the institutional importance of professional genealogists, while later accounts describe training, examination and hereditary transmission of expertise in different periods. The social authority of the Panjikar depended on both possession of records and recognised competence in interpreting them. This combination made genealogical knowledge a specialised profession. Because records

could be distributed among families of Panjikars, the archive was never a single central registry in the modern bureaucratic sense; it functioned as a network of manuscript repositories and expert custodians.

31.7 Manuscript materiality and the problem of copies

Panji records were preserved on palm leaf and on indigenous papers, and the transition between writing materials is itself part of their history. FamilySearch's digitised Koilukh collection, for example, preserves Maithil Brahman genealogical records dated mainly from the eighteenth century onward and notes both palm-leaf and paper traditions. Such collections are invaluable, but they also demonstrate why the historian must distinguish physical object from genealogical content. A late copy can transmit an older pedigree; a copied line can introduce an error; a damaged folio can break a chain; and recopying can standardise a name that once had variant spellings. The archive should therefore be read as a manuscript tradition with transmission histories, not as a database whose entries are automatically uniform.

31.8 Mūla: territory encoded in genealogy

One of the Panji tradition's most important social innovations was the linking of descent to territorial memory through mūla. A mūla identifies a lineage through an ancestral point of origin, often expressed through a founding ancestor associated with a place. Pandey's reconstruction emphasises this convergence of genealogy and territory: corporate identity was not only a matter of abstract gotra but was grounded in remembered settlement histories. Mūla therefore allows the historian to study how villages became genealogical reference points, how migration was remembered, and how territorial origin could persist as identity after descendants moved elsewhere. It is not a modern address field; it is a historical category of origin whose meaning depends on the Panji tradition itself.

31.9 Gotra, pravara and mūla are not interchangeable

The genealogical language of Mithila combines categories with different histories. Gotra and pravara belong to much older Brahmanical systems of patrilineal and ritual identification. Mūla, by contrast, is a territorial-genealogical device central to the corporate history reconstructed through the Panjis. A household could therefore share a gotra with many distant families while belonging to a particular mūla that located its remembered founding line. Treating these categories as synonyms erases precisely what the Panji added: a fine-grained mechanism for distinguishing lines within broader ritual descent. The same caution applies to later grades and sub-castes, which should not be projected back into the first moment of registration.

31.10 Marriage regulation and Siddhānta

The Panji achieved its greatest practical force through marriage regulation. Genealogical knowledge was used to determine whether a proposed match fell within prohibited relationships and whether the relevant pedigree claims could be reconciled. In later practice the Panjika's determination was embodied in forms of genealogical certification commonly discussed under the term Siddhānta. The document should be understood as a social decision produced from a record, not as a timeless ritual object. Its authority depended on the recognised genealogy, the competence of the Panjika and the willingness of families to treat the result as binding. Marriage thus became a principal arena in which documentary knowledge shaped everyday social reproduction.

Figure 121 — From lineage markers to matrimonial verification

31.11 Prohibited relationship and the logic of verification

The Panji system is often described as a mechanism for preventing marriage between persons considered too closely related within the regulated community. Historically, however, the important point is institutional rather than biological. The system worked through culturally defined genealogical rules, remembered descent and documentary comparison. It did not measure genetic distance, and its categories cannot be translated directly into modern population genetics. Nor should a historical Siddhānta be treated as a contemporary legal certificate without verification. The Panji is most accurately understood as an indigenous technology of kinship governance: it transformed rules of relationship into a documentary and professional procedure.

31.12 The archive as social memory

A Panji entry does more than connect two names. Repeated pedigrees preserve remembered migrations, marriages, status claims, scholarly reputations and connections between villages. In that sense the corpus is an archive of social memory. Yet memory is selective. Genealogies tend to privilege lines useful to descent and marriage; they can omit people who did not matter to the institutional purpose; and their representation of women is often relational rather than biographical. The historical value of the corpus lies not in pretending that it records all of society equally, but in asking what kinds of memory the institution considered necessary to preserve. What the record omits can be as revealing as what it names.

31.13 Rank, grade and historical change

The Panji tradition did not merely record a pre-existing, eternally fixed hierarchy. Scholarship on medieval Mithila shows that genealogical regulation participated in the formation and differentiation of status. Ranked grades within the Maithil Brahman community changed over time and could acquire increasingly corporate consequences through marriage. The historian must therefore analyse rank terms as dated institutional categories. A label attested in a later manuscript or ethnography cannot automatically be inserted into the fourteenth-century foundation narrative. The Panji is important precisely because it allows

social classification to be studied as a process: categories could be created, reinterpreted, enforced and transformed through successive generations of record keeping.

31.14 Śrotriya: the necessary chronology correction

This volume adopts a specific Panji-based chronological correction: Śrotriya should not be projected as a fixed Maithil Brahman sub-caste into the medieval period. The Sanskrit word śrotriya is much older and could denote a Brahman recognised for Vedic learning or qualification, as Chapter 30 explained. The later Mithila Śrotriya sub-caste is a different historical formation. The Panji evidence used in this project places its emergence as a distinct sub-caste around 1800 CE, after the period of Madhav Singh, rather than in the fourteenth or seventeenth century. This distinction is not semantic pedantry; it prevents a later corporate category from rewriting the social history of earlier centuries.

Figure 122 — Panji institutions changed over time

31.15 Women in a patrilineal archive

Panji records are organised predominantly through patrilineal descent, which affects how women appear. A woman may be visible because her marriage connects two pedigrees, because she is identified as a daughter or wife, or because a disputed relationship makes her genealogically significant. Such visibility is not equivalent to a biography. The archive therefore simultaneously preserves crucial evidence for women's marital networks and reproduces a male-centred documentary structure. A gender-sensitive reading should use marriage entries to reconstruct mobility, alliance and household connection while resisting the assumption that women's sparse naming indicates low social importance. Their labour in maintaining households, ritual relationships and kin networks was far greater than the formal genealogical record usually shows.

31.16 Kayastha Panjis and the broader institution

The Panji tradition is not solely a Maithil Brahman phenomenon. Genealogical records were also maintained among Maithili Karna Kayasthas, and Binod Bihari Verma's survey demonstrates the importance of Kayastha Panji manuscripts as a parallel corpus. This broader evidence changes the social interpretation of

the institution. Genealogical regulation in Mithila was part of a wider culture of documentary descent among literate status communities, not only an internal Brahman ritual device. The forms, categories and histories of Brahman and Kayastha Panjis should not be assumed identical, but comparison allows the historian to ask how state service, literacy, marriage and territorial memory produced related archival practices.

31.17 Royal patronage and the politics of genealogy

Genealogical regulation required authority. The fourteenth-century association with the Tirhut court is therefore not incidental. Royal backing could give social force to enumeration, define recognised experts and encourage families to submit to common rules. Later ruling houses inherited and reshaped this institutional environment. The relationship was mutually useful: genealogy gave the court an organised language for recognising elite households, while court patronage gave genealogists status and continuity. Yet the Panji should not be reduced to royal propaganda. Once embedded in marriage practice, it developed a social life that exceeded any single dynasty and could survive political transitions that altered the formal structure of the state.

31.18 From Karnata to Oiniwar and later courts

The fall of Karnata political power did not end the genealogy-based social order. Pandey's study emphasises how succeeding Maithil Brahman ruling houses maintained and extended the machinery through which Brahman identity, territory and authority were organised. This continuity helps explain the Panji's durability: it was not tied exclusively to one founder king but became useful to later courts and communities. At the same time, continuity should not be confused with stasis. Successive regimes could alter patronage, rank, the personnel of genealogical administration and the political meanings attached to learned lineages. The archive therefore records a long institutional history in which the framework endured while its social content changed.

31.19 Panjikars under the Darbhanga Raj order

Later descriptions of Panjikaṛ organisation belong to a different historical phase from fourteenth-century formalisation. Ugra Nath Jha records traditions of professional training and examination associated with the Darbhanga Raj period, showing that genealogical expertise could be institutionalised through court-connected procedures. Such evidence is valuable for the history of the profession, but it must remain in its own chronological layer. It cannot prove that the same examination, hierarchy of offices or documentary routines existed in Harisimhadeva's reign. The contrast itself is instructive: a medieval system of genealogical regulation was repeatedly bureaucratised and professionalised under later political conditions.

31.20 Saurath Sabha and public matrimonial space

Saurath Sabha became one of the most visible public settings in which Panji expertise and marriage negotiation interacted. Families, intermediaries and Panjikars used the gathering to identify possible matches and verify relationships. Yet the antiquity of the Sabha in its later documented form should not be assumed from the antiquity of the Panji system. The institution of a genealogy can precede, outlive or change independently of a particular assembly site. Historically, Saurath is best studied as a later public interface of the Panji order: it spatialised a documentary system by bringing pedigrees, professional verification and matrimonial negotiation into a shared arena.

31.21 Genealogy is not genetic proof or legal title

Modern digitisation makes Panji records easier to search, but accessibility can encourage category mistakes. A historical genealogy is not a DNA test. It does not automatically establish biological paternity, legal inheritance, caste certification or title to property. Its entries were created for historically specific social purposes and require source verification. This distinction is especially important when old records concern living families. The responsible historian treats the Panji as evidence for recorded genealogy and social classification, compares it with other sources, and avoids transforming an archival statement into a modern legal or biological judgment for which the document was never designed.

31.22 Dūṣaṇ records: evidence without inherited stigma

Some Panji traditions include dūṣaṇ or disqualification categories that recorded perceived defects, breaches or status problems relevant to historical marriage regulation. Such records can illuminate the political economy of reputation: communities used documentary memory not only to validate descent but also to sanction conduct and classify families. They are ethically difficult sources. A historical dūṣaṇ entry should never be used to stigmatise a living person, family or village. Its proper use is analytical: to reconstruct what earlier institutions considered disqualifying, how reputational sanctions circulated, and how social power could be exercised through archival classification.

31.23 Migration encoded as remembered origin

Because mūla and pedigree preserve origin narratives, Panji records can help trace migration and settlement. They show how a family's identity could remain attached to an ancestral village after descendants moved, acquired new patronage or established branches elsewhere. This makes the corpus especially useful for the connected history of Mithila across present-day administrative boundaries. Yet migration must be reconstructed cautiously. A genealogical origin is not necessarily the same as the first archaeological settlement of a group, and a remembered founding ancestor may represent the point at which a lineage became institutionally visible rather than its biological beginning. Panji geography is therefore historical social geography, not a substitute for archaeology.

31.24 Mithila across the India–Nepal border

The historical region of Mithila extends across the modern India–Nepal border, whereas the Panji institution predates that boundary. Genealogical and marriage networks therefore provide evidence for social continuities that do not map neatly onto modern states. Families, scholars and marriage partners could move within a cultural region later divided by national administration. At the same time, the historian must not use the Panji to erase political difference. Nepalese and Indian regimes created distinct legal and administrative environments in the modern period. The archive is most valuable for showing how kinship and territorial memory interacted with, crossed and sometimes adapted to changing political boundaries.

31.25 Gaps, variants and contradiction are historical evidence

No large manuscript genealogy is free from gaps. Names can be omitted; spellings vary; generations can be compressed; copies can disagree; a lineage can appear under different territorial labels; and later annotations may coexist with older text. These are not reasons to discard the archive. They are reasons to use manuscript method. Variant readings can reveal how knowledge was transmitted and where institutional interests were strongest. A pedigree supported by independent copies has a different evidentiary weight from an isolated late entry. The mature use of Panji therefore replaces the search for one infallible master list with

comparison among witnesses, attention to handwriting and material date, and explicit statements of uncertainty.

31.26 Cross-verification with inscriptions, chronicles and local records

Genealogical claims become historically stronger when they can be compared with sources created for different purposes. Copper-plate grants may confirm a learned lineage or village; court chronicles can anchor patronage; literary texts can illuminate titles and intellectual networks; revenue records can document later settlement; and local manuscripts can clarify branches omitted from a Panji copy. Cross-verification does not require every name to appear everywhere. Rather, it tests whether the social world implied by the genealogy is compatible with independently dated evidence. This method is especially important for prominent scholarly or ruling families whose later prestige could encourage retrospective elaboration.

31.27 Digitisation as a new phase in Panji history

Digitisation is not external to the history of the Panji; it is the latest transformation of the medium through which genealogical knowledge survives. Photographic imaging reduces handling of fragile palm-leaf and paper manuscripts, creates distributed backups and allows comparison across collections. Search systems can expose patterns that are difficult to see by reading folios sequentially. Yet digitisation also creates new risks: cropped images can detach entries from context, transcription can normalise uncertain readings, and searchable databases can tempt users to treat an index as the source itself. Digital scholarship must therefore preserve links between search results and page images, record provenance and retain uncertainty.

31.28 Custodianship, access and intellectual property

Panjikar families have historically treated their manuscript knowledge as professional capital. Modern researchers have therefore encountered legitimate tensions between public preservation and custodial control. Pandey notes the difficulty of obtaining access to complete Panji sets and acknowledges the digitised records supplied for his research; Videha subsequently placed important Panji material into wider public circulation. This history should be treated with respect for both preservation and provenance. Open access does not erase the labour of custodians, while custodianship cannot substitute for conservation when unique manuscripts are endangered. A sustainable future requires attribution, preservation-quality imaging, ethical access and clear separation between scholarly use and commercial or discriminatory misuse.

Figure 123 — The Panji as a social-information network

31.29 What historians can and cannot infer

Used critically, the Panji can reconstruct marriage networks, lineage differentiation, territorial memory, professional genealogy, changing status categories and the long interaction between households and courts. It can sometimes help trace scholarly networks and migration. It cannot, by itself, reconstruct the entire population of Mithila, prove genetic relationships, date every remembered ancestor, or demonstrate that a later category existed from the beginning of the system. Nor should absence from one manuscript be treated as proof that a person or line did not exist. The corpus is powerful because it is institutionally structured, and limited for the same reason: it records what the institution needed to know.

31.30 Conclusion: a living archive of social formation

The Panji tradition is one of Mithila's most important archives because it records social formation from within a system that actively shaped the relationships it documented. Its fourteenth-century formalisation linked genealogy, territory and authority; Panjikars transformed manuscripts into decisions; marriage regulation gave the archive everyday force; later courts and assemblies professionalised its use; and successive copies incorporated changing vocabularies of status. That history also demands chronological discipline. Gotra, mūla, rank and later sub-caste labels belong to different layers, and the Śrottriya sub-caste should not be projected before the Panji evidence that supports its emergence around 1800. Read in this way, the Panji is neither mythic antiquity nor a modern database. It is a living manuscript institution whose changes are themselves part of Mithila's social history.

Table 31.1 — Panji evidence: historical use and limit

Evidence	What it can show	What it cannot show by itself
Panji manuscripts	Pedigrees, mūla, relationships, later classifications and manuscript transmission	The physical date of a surviving copy is not automatically the date of every entry it contains.
Fourteenth-century institutional history	Context for formalisation of genealogical regulation under	Does not prove that every later Panjika procedure or

Evidence	What it can show	What it cannot show by itself
	Tirhut/Karnata authority	rank category existed in the founding phase.
Panjikar practice	How records were interpreted, copied, verified and used in marriage decisions	Late ethnographic practice cannot be projected unchanged into medieval centuries.
Saurath and marriage assemblies	Public interaction between genealogy, matchmaking and professional verification	The antiquity of the Panji does not by itself establish the antiquity of every later assembly custom.
Mūla and territorial memory	Remembered origin, lineage branching and migration within Mithila	Not a substitute for archaeology or proof of the earliest biological origin of a group.
Rank and dūṣaṇ categories	Historical mechanisms of status differentiation, sanction and reputation	Must not be used to stigmatise living persons or projected backward without dated evidence.
Śrottriya evidence	Supports a distinct Maithil Brahman sub-caste around 1800 in this project's Panji chronology	Earlier Sanskrit śrottriya denotes learning/qualification and is not proof of the later sub-caste.
Digitised collections	Preservation, comparison, indexing and wider scholarly access	Search results are not substitutes for manuscript images, provenance or expert verification.

Chapter 32 — Women, Marriage and Property in Medieval Mithila

Women's social and economic history in medieval Mithila cannot be reconstructed by taking a single legal rule and treating it as a transparent description of life. The most articulate surviving materials are juristic: Sanskrit digests that classify marriage, gifts, inheritance, maintenance and household obligations. Those texts are indispensable because they preserve categories and arguments used by learned specialists, yet they are normative and selective. Genealogical records illuminate marriage relationships in the communities they document but usually privilege patrilineal continuity. Agrarian records and material history reveal the economy in which households functioned while often leaving women unnamed. Later colonial courts preserve a history of how "Mithila law" was read, but they belong to a much later evidentiary moment. This chapter therefore reconstructs women, marriage and property through a chronology firewall: every claim is tied to the kind and date of its source.

32.1 Women's history as a source problem

The first difficulty is visibility. Medieval archives were not designed to answer modern questions about women's work, autonomy or ownership. A jurist asked which rule applied to a dispute; a genealogist recorded descent and marriage eligibility; a grant recorded title, privilege or revenue; a literary text pursued aesthetic, devotional or political purposes. Women appear differently in each genre, and silence has different meanings. An unnamed cultivator's wife in an agrarian record is not evidence that women did no agricultural work. A detailed rule on a widow's succession is not evidence that every widow successfully exercised the right contemplated by the jurist. Historical reconstruction must therefore distinguish presence in the archive from presence in society. The chapter uses explicit statements where available and cautious structural inference where direct testimony is absent.

32.2 Normative rule is not observed practice

Dharmaśāstra and the regional nibandha tradition organise conduct into legal and ritual categories. Their value is greatest when they are read as arguments about legitimate order rather than as a statistical description of actual behaviour. A rule may respond to a contested practice; a prohibition may reveal anxiety precisely because the prohibited act occurred; a ranked list of marriage forms may preserve an inherited scholastic classification rather than a map of locally common weddings. Conversely, customary behaviour could operate without leaving an equally elaborate textual theory. The proper historical question is therefore twofold: what kinds of claims did learned authorities recognise, and what independent evidence indicates how households actually arranged marriage, property and support? Keeping those questions separate prevents both romanticisation and over-legalisation of medieval social life.

32.3 The chronological frame: Karnata, Oiniwar and later medieval Mithila

The chapter's central frame runs from the Karnata political order into the Oiniwar period and later medieval legal-literary culture. These centuries produced major Mithila-based juristic works and saw the consolidation of manuscript, scholastic and genealogical institutions. The political transitions did not create one uniform family regime. Courtly centres, learned Brahmanical households, landed groups, artisans, service communities and agrarian labouring populations possessed unequal resources and left unequal archives. Regional boundaries also shifted. "Mithila" in a legal school, a genealogical archive or a political narrative is therefore not automatically identical with every settlement in the wider north-Bihar and Nepal-Tarai cultural

zone. The chapter uses the regional label carefully and marks community-specific evidence whenever its scope is narrower than the geographic region.

32.4 Mithila's legal-digest tradition

Caṇḍeśvara Ṭhakkura, active in the early fourteenth-century political-intellectual world of Tirhut, systematised legal and household subjects in the Ratnākara corpus. The Vivādaratnākara became especially important for partition, inheritance and dispute, while related works addressed domestic and ritual obligations. Later Mithila scholarship, including Vācaspati Mīśra's Vivādacintāmaṇi, continued an intensive regional tradition of digesting earlier authorities and resolving competing rules. These texts allow us to see sophisticated argument about marriage, women's property, heirs, maintenance and household claims. Their authority, however, is an intellectual-historical fact, not proof that every social group followed each formulation in identical fashion. The safest use is to reconstruct a learned legal vocabulary and then compare it with genealogical, economic and later reception evidence.

Figure 124 — Reconstructing women's history requires layered evidence

32.5 Marriage as household formation and kin alliance

Marriage joined persons, households and kin networks. In an agrarian society, the alliance had economic consequences even when the surviving text framed it in ritual language. It could affect residence, transfers of gifts, claims to support, obligations between affines, the placement of children in lines of succession and the practical availability of labour. For elite and genealogically recorded groups, marriage could also carry consequences for pedigree and social standing. None of these functions reduces marriage to a property transaction. Rather, marriage was a social institution in which ritual status, kinship, household economy and gendered expectations intersected. The sources must therefore be read across domains: a juristic category describes lawful form; a Panji relationship documents a connection; an inheritance rule identifies potential successors; and household economy determines what the right could mean materially.

32.6 Normative forms of marriage

Medieval Mithila jurists inherited the wider Dharmaśāstra classification of marriage forms and discussed their relative approval, conditions and consequences. Such taxonomies mattered because later inheritance arguments could distinguish between marriages placed in approved and disapproved categories. But the classification is not a frequency table. It tells us how jurists sorted possible unions, not how many marriages of each type occurred in a village or century. Nor should modern labels such as “love marriage” or “arranged marriage” be imposed mechanically on categories constructed for different ritual and legal questions. Historically, the classification is strongest evidence for the conceptual grammar within which learned disputation operated. Social practice must be sought through other traces, especially kinship records, local custom and the economic circumstances of households.

32.7 Guardianship, consent and the danger of simple binaries

Texts discussing who may give a bride, the suitability of spouses and the circumstances under which a woman might act outside the expected sequence of guardianship reveal a field of regulated choices. They should not be compressed into the binary claim that medieval women either “had consent” or “had no consent.” Juristic reasoning often distinguishes authority to perform a legally or ritually effective act from the lived negotiation through which a marriage was arranged. Household seniority, kin strategy, age, widowhood, property and local custom could all alter practical bargaining power. The sources rarely preserve the woman’s own speech in a form that allows confident reconstruction of negotiation. A responsible history therefore describes the formal framework, records explicit exceptions, and avoids converting silence about personal preference into proof of either complete autonomy or complete absence of agency.

32.8 Marriage gifts and the category of *strīdhana*

One of the clearest ways women enter the legal archive is through *strīdhana*, a technical category of women’s property. Later printed translation of the *Vivādacintāmaṇi* enumerates a cluster of gifts connected with marriage and close kin, including gifts associated with the nuptial ceremony and bridal movement as well as gifts from father, mother and brother. The important historical point is not merely the list. Jurists treated some assets as capable of being classified separately from an undifferentiated household estate, and they debated who could succeed to those assets. At the same time, “*strīdhana*” should not be used as a synonym for everything a woman possessed, used or helped produce. Technical classification, actual control and household access were related but distinct questions.

32.9 The sixfold gift language and what it can show

The familiar sixfold formulation preserved in the Mithila legal tradition places several kinds of gifts around the marriage process and the natal family. It demonstrates that juristic thought recognised multiple channels by which resources might be assigned to a woman and that the source of an asset could matter legally. It does not reveal the average monetary value of such gifts, whether a particular household could afford them, or how readily a woman could convert a formally recognised asset into independent economic power. Gift language also spans objects of very different scale, from ornaments and movable valuables to resources whose later legal treatment could become more complicated. The historian should therefore use the list as a map of recognised acquisition channels and not as a quantitative description of medieval marriage expenditure.

32.10 Property as a bundle of rights

“Property” is too blunt a word unless the underlying powers are separated. Possession, use, income, management, alienation, security for debt and succession after death need not belong to the same person in the same degree. A widow might enjoy or manage an asset without having an unrestricted power to alienate its corpus; a gift might be classified as a woman’s separate property yet still become the subject of kin claims after her death; household resources could be used collectively without becoming strīdhana. This bundle-of-rights approach helps reconcile apparently conflicting sources. A text that recognises a woman as heir does not automatically answer how property was managed in daily life, while evidence of male household management does not by itself erase a legally differentiated female claim. The categories must be kept analytically distinct.

Figure 125 — Property is a bundle of distinct rights			
Property source	Possession / use	Power to transfer	Succession after death
Marriage gifts	may be separately held	depends on category / rule	specified kin or marital line
Inherited assets	may carry use or title	not always identical to use	depends on property and heirs
Household resources	often shared in practice	family or title constraints	not automatically strīdhana
Maintenance claim	economic support right	usually not ownership of corpus	ends or changes by rule/context
Analytical rule: never treat “property” as one undifferentiated legal power.			

Figure 125 — Property is a bundle of distinct rights

32.11 Movable and immovable property

Later judicial readings of Mithila authorities repeatedly encountered distinctions between movable and immovable assets, especially when discussing women’s inheritance and the scope of powers attached to property. These later decisions are not medieval evidence in themselves, but their difficulty is historically instructive: the received textual tradition did not reduce women’s property to one simple formula. In a medieval household, movables such as jewellery, utensils, textiles, livestock or cash-like valuables could circulate differently from rights in land or houses. Land, moreover, was embedded in agrarian obligations, lineage claims and revenue structures. The historian should therefore avoid transferring a conclusion about one asset class to all property. Where a medieval digest expressly distinguishes categories, that distinction is primary; where only later courts articulate it, the point belongs to reception history unless earlier textual support can be demonstrated.

32.12 Inherited property is not automatically strīdhana

A second essential distinction is between acquisition by inheritance and acquisition within the technical categories of women’s separate property. Different schools and authors classified inherited assets differently, and later courts struggled with the consequences of those classifications. For social history, the secure

proposition is narrower: women could appear in chains of succession, but the legal character and powers attached to the inherited asset had to be determined from the relevant rule, property type and kin situation. It is therefore misleading to say either that “women did not inherit” or that “all inherited property became absolute female property” across medieval Mithila. Both statements erase the juristic distinctions preserved by the sources. The chapter instead follows the route of each claim: acquisition, enjoyment or management, alienation where discussed, and succession after the woman’s death.

32.13 Widowhood, succession and management

Widowhood changed a woman’s position within both kinship and property relations. Juristic texts had to decide who represented the deceased man’s line, who maintained dependants and who succeeded when sons or other heirs were absent. The very elaboration of such questions shows that widowhood was not legally invisible. Yet a formal place in succession could coexist with practical dependence on male relatives, pressure over residence, or restrictions on dealing with particular assets. Conversely, the existence of household hierarchy should not be converted into an assumption that every widow was economically dispossessed. The evidence supports a differentiated history in which age, children, property class, separation or jointness of the household, natal support and local authority all mattered. Where later courts quote Mithila authorities, they show how these problems were subsequently interpreted, not a photograph of medieval widowhood.

32.14 Daughters in succession

Daughters also appear within the legal architecture of succession, but position and priority can depend on the specific source and circumstances. Later Anglo-Hindu adjudication of Mithila law debated distinctions among unmarried and married daughters and the consequences of widowhood or issue. That debate confirms the survival of a regionally identified jurisprudential tradition, while also warning us not to import nineteenth- and twentieth-century judicial formulations unchanged into earlier centuries. For the medieval period, the safer conclusion is that daughterhood was a recognised relationship capable of carrying inheritance significance within juristic reasoning. The practical value of that claim depended on the estate available, competing heirs, the woman’s household position and enforceability. Genealogies can sometimes establish relationships but rarely disclose the full economic content of a daughter’s claim.

32.15 Natal kin after marriage

Marriage did not erase the natal family. The very classification of gifts from father, mother or brother presupposes continuing economic ties across the marital transition. Natal relatives could remain sources of support, ritual connection and property transmission; in moments of widowhood or dispute those ties could become especially important. At the same time, the degree of continuing connection varied by distance, resources, rank and local custom. A legal list of permissible or recognised gifts should not be transformed into an assumption of equal natal support for all women. Poor households faced different constraints from landed or court-connected families. The social-history value of the legal category lies in proving that natal and marital kin were not mutually exclusive spheres. Women stood at the junction of both networks, though not necessarily with equal power within either.

32.16 Maintenance as an economic claim

Maintenance deserves separate treatment because subsistence rights are economically significant even when they do not amount to title over the underlying property. Juristic traditions discuss obligations to support wives, widows and other dependants within household and kin structures. Such claims could shape

access to food, clothing, residence and the income needed for daily life. For many households, maintenance may have mattered more immediately than an abstract question of alienable ownership. Yet formal entitlement is only one side of the history. Enforcement depended on assets, household cooperation and local power. The chapter therefore treats maintenance as a distinct component of women's economic position: neither trivial because it is not full ownership, nor equivalent to ownership because it may give no general power to sell or permanently transfer the property from which support is drawn.

32.17 Additional marriage, supersession and compensation categories

Dharmaśāstra-derived literature also discusses the circumstances and consequences of a husband taking another wife, sometimes framing compensation or property assigned to the existing wife through technical categories. The presence of such rules is valuable evidence that jurists contemplated conflict inside polygynous household arrangements and attempted to regulate economic consequences. It is not a warrant to describe polygyny as universal, nor to assume that every woman received the compensation contemplated by the text. Frequency cannot be calculated from a prescriptive rule. What can be said is that marriage hierarchy created recognised legal problems concerning support, gifts and household status. These rules make visible a dimension of women's economic vulnerability while simultaneously showing that juristic reasoning did not treat the displaced wife as having no claim whatsoever.

32.18 Debt, pledge and household boundaries

Property disputes often sharpened at the boundary between household need and individual claim. Assets could be sold, pledged or used to meet obligations, and later interpreters of Mithila texts repeatedly asked whether a husband or other relative could dispose of property associated with a woman. The medieval materials need to be read with exact attention to the property category and the reason for the transaction. Emergency support, ritual duty, ordinary debt and voluntary alienation were not necessarily treated alike. For social history, the larger lesson is that household economy was not a frictionless common pool. Jurists drew boundaries precisely because resources could be contested. A woman's formally differentiated asset might nevertheless be vulnerable to household pressure, while household property used by a woman did not automatically become her separate property. The distinction between legal title and economic dependence remains crucial.

32.19 Succession after a woman's death

The destination of property after a woman's death is one of the best tests of whether a category was legally differentiated. Mithila jurists and later readers distinguish succession according to the source and legal character of the woman's property and, in some formulations, according to the recognised form of marriage. Children, husband, natal relatives and other heirs can therefore enter different sequences. This complexity matters historically because it contradicts any model in which marriage simply transfers all of a woman's resources permanently into the husband's undifferentiated estate. It also contradicts the opposite model in which every asset remains wholly detached from marital kin. The sources describe intersecting channels of transmission. To reconstruct them responsibly, each statement must specify the kind of property, the relevant kin configuration and the date of the authority being used.

Figure 126 — Marriage links two kin networks without erasing separate property claims

32.20 Marriage regulation and the Panji tradition

The Panji tradition discussed in Chapter 31 adds a different kind of evidence. Its genealogical logic could make marriage a documented relation between lineages and could place specialised knowledge in the hands of Panjikars. That evidence is especially useful for the communities whose pedigrees were actually maintained. It must also be periodised. The medieval institutionalisation of genealogy cannot be used to project every later marriage rank or sub-caste label backward into the fourteenth or fifteenth century. In particular, this project retains its Panji-based chronological conclusion that Śrōtriya emerges as a distinct Maithil Brahmin sub-caste around 1800 CE; it is not treated here as a fixed medieval category. Genealogical continuity and later social classification are therefore analysed as related but historically non-identical processes.

32.21 Panji evidence is community-specific

A further limit follows from the archive's social distribution. Panji materials are rich for particular genealogically organised groups, but they do not provide a complete register of every woman, marriage or household in medieval Mithila. Using them as if they represented the entire regional population would privilege communities that produced and preserved written pedigrees over those whose kinship histories were maintained orally or in other documentary forms. The same caution applies to legal digests produced by learned elites. The chapter therefore uses Panji evidence to illuminate mechanisms of recorded alliance, prohibited proximity, lineage memory and later classification within its documented social field. It does not make the absence of a community from a Panji manuscript evidence of social absence, nor does it treat one group's marriage procedures as a regional universal.

32.22 Women's visibility in patrilineal records

Patrilineal genealogy creates a paradox. Marriage makes women indispensable to the reproduction and connection of lineages, yet records organised around male descent may abbreviate women's identities. A daughter may be significant because her marriage links two pedigrees while the archive preserves less information about her own economic life than about male ancestors. This archival asymmetry should itself be treated as evidence of what the institution was designed to remember. It is not proof that women lacked

social importance. Nor is every later expansion of female names evidence for an earlier practice. Where manuscripts provide women's names, marital links or kin affiliations, those details should be retained exactly. Where they do not, the historian must resist filling the silence with invented biographies or presumed property arrangements.

32.23 Household labour and the agrarian economy

Agrarian society depended on household labour, but written legal and revenue sources rarely enumerate every task by gender. Women's work could include processing grain, tending animals, managing food stores, textile production, water and fuel work, childcare, ritual preparation, market-related handling of goods and, in many environments, direct participation in cultivation. The precise combination varied by ecology, class and household organisation. Because the medieval Mithila archive does not provide a comprehensive labour census, the chapter does not assign a universal task list to all women. Instead it makes a structural point: property rights operated inside a productive household economy, and economic contribution cannot be measured solely by whose name appeared in title documents. Labour history therefore broadens the meaning of material participation without converting plausible regional patterns into unsupported individual claims.

32.24 Elite texts and non-elite custom

The social reach of Sanskrit legal scholarship was uneven. A learned digest could influence adjudication, elite household conduct and later legal interpretation while coexisting with local custom among cultivators, artisans, pastoralists, forest-edge communities and service groups. Custom itself was not static or isolated from elite norms; interaction moved in both directions, and disputes could bring local practice into dialogue with textual authority. The evidentiary problem is that non-elite women are often least visible in the surviving learned corpus. A history that quotes only jurists therefore risks turning the archive of one stratum into the society of an entire region. This chapter uses the legal tradition for what it demonstrably supplies—categories, debates and claimed norms—and marks the wider social field as more diverse wherever direct local evidence is insufficient.

32.25 Rank, resources and marriage choice

Marriage strategy was shaped by resources as well as ideals. Landed households could use marriage to consolidate alliances, preserve status or connect networks of learning and office. Households with fewer resources confronted different constraints involving distance, gifts, labour, maintenance and the availability of suitable partners. Genealogical regulation could narrow the eligible field for some communities, while local custom organised marriage differently elsewhere. Consequently, “medieval Mithila marriage” cannot be represented by a single elite ceremonial model. Even within one normative tradition, jurists discuss exceptions and competing conditions. Social rank matters not because it creates perfectly sealed worlds, but because it changes what options are materially feasible. A useful reconstruction therefore places marriage rules alongside property distribution, household economy and the uneven documentary visibility of different groups.

32.26 Widowhood was not a single economic condition

The word “widow” identifies marital status but does not by itself describe an economic position. A widow with minor children, movable property and strong natal support occupied a different situation from a childless widow dependent on affinal kin; a woman connected to landed property faced different issues from one in a labouring household with few transferable assets. Juristic texts differentiate heirs and property

categories, while later courts expose how disputed the practical consequences could become. Ritual prescriptions may also have shaped status without determining the whole material economy. The chapter therefore rejects both a uniformly helpless widow and an anachronistically autonomous property-holder as universal types. Medieval evidence supports multiple possible positions structured by kin, assets, household form, age, children and the enforceability of claims.

32.27 Colonial “Mithila law” as reception history

Nineteenth- and early twentieth-century courts repeatedly cited texts such as the *Vivādacintāmaṇi* and *Vivādaratnākara* when deciding inheritance and women’s property disputes among parties treated as governed by the Mithila school. One Calcutta decision described the *Vivādacintāmaṇi* as an authority of the highest standing in that school; later Patna decisions continued to debate daughters, widows and *strīdhana* through regionally identified doctrine. These cases matter because they preserve quotations, textual hierarchies and the history of legal reception. They do not prove that the judicial rule announced in 1885 or 1928 had operated unchanged in a fourteenth-century village. Colonial adjudication selected, translated and systematised Sanskrit authorities within a new institutional setting. It must therefore be placed after, not merged with, the medieval evidence.

Figure 127 — A chronology firewall for women’s legal history

32.28 Modern statutes are not medieval evidence

Modern statutory reforms profoundly changed inheritance and gendered property rights in South Asia. They are essential for legal history, but they cannot be used to describe medieval practice backward. The same applies to modern judicial concepts, registration systems, constitutional equality and contemporary categories of marital property. A historian may compare periods, but comparison requires a visible break between them. This chapter therefore stops short of turning present law into a measure of what a medieval woman “really owned.” Instead, it asks what the medieval sources meant by the categories they used, how later courts received those categories, and where modern law created a different legal framework. The chronology firewall is especially important because familiar modern words—owner, heir, widow, daughter, gift—can conceal major changes in the bundle of rights attached to them.

32.29 What can and cannot be inferred securely

Several conclusions are secure. Medieval Mithila possessed an advanced juristic tradition that treated marriage, women's property, succession and maintenance as distinct legal problems. Women could be recognised through multiple channels of acquisition and inheritance; marriage connected rather than simply erased natal and marital kin relations; and property claims varied by source, asset and heir configuration. Genealogical institutions add evidence for marriage regulation in the communities they record. Less secure are claims about frequency: how common each marriage form was, how often women successfully enforced a right, the average value of gifts, or the exact division of labour in every social stratum. Those questions require evidence the surviving archive does not supply uniformly. The chapter therefore prefers bounded conclusions to a false completeness built from retrospective generalisation.

32.30 Conclusion: gender, kinship and economy as connected histories

Women's history in medieval Mithila emerges most clearly when legal categories are connected to kinship and economy without being mistaken for either. Marriage created alliances and household obligations; gifts and inheritance opened differentiated property channels; maintenance could matter without conferring full ownership; widowhood and daughterhood carried legal significance that varied by context; and genealogical institutions recorded some marriage networks while leaving large parts of society outside their documentary frame. The central methodological result is equally important: later "Mithila law," modern caste classifications and current statutes must not be projected backward. By dating each source and separating norm, practice, reception and reform, it becomes possible to recover a more precise history—one in which women are neither absent from property relations nor imagined as possessing a uniform modern-style legal status across all medieval households.

Table 32.1 — Women, marriage and property: evidence, secure use and limit

Evidence	What it can show	Secure historical use	Limit of inference
Vivādaratnākara	Juristic reasoning on partition, inheritance and dispute	Reconstruct early-14th-century learned legal categories and arguments	Does not measure frequency or compliance in all households
Vivādacintāmaṇi	Later Mithila doctrine on women's property, heirs and related disputes	Trace later-medieval regional jurisprudence and textual interpretation	Later printed translations and court use must be dated separately
Other nibandha / household texts	Marriage, domestic duties, ritual and household regulation	Recover the normative vocabulary linking marriage and household order	Elite learned prescription is not a complete social survey
Panji / genealogical manuscripts	Recorded descent and marriage connections in documented communities	Study lineage memory, alliance and marriage regulation with manuscript dating	Not a census of all communities; women may be abbreviated in patrilineal records
Agrarian / land documentation	Title, revenue, grants, settlement and resource structures	Place household property within the regional political economy	Often under-records women's labour and informal access to resources
Later colonial court decisions	How courts ranked and interpreted texts called "Mithila law"	Study reception history and recover quoted doctrinal debates	A 19th- or 20th-century ruling is not direct evidence of medieval practice
Material /	Production,	Test what formal claims could	Usually cannot identify

Evidence	What it can show	Secure historical use	Limit of inference
household economy	consumption, movable goods and labour constraints	mean in everyday economic life	an individual woman's legal title without documents
Modern statutory law	Later transformation of inheritance and gendered rights	Mark change over time and prevent anachronism	Must never be projected backward as medieval law

Chapter 33 — Karnata and Oiniwar-Period Social Economy

The Karnata and Oiniwar centuries are often narrated through rulers, invasions and genealogies, yet their historical significance also lies in the institutions that converted land, labour, knowledge and movement into durable social power. The Karnata kingdom, conventionally dated from Nanyadeva's establishment of power in 1097 to the Tughluq conquest of 1324, was centred on Simraungadh and linked the middle Gangetic plain to the Himalayan foothills. The Oiniwar order that followed operated through smaller, shifting centres and changing relations with stronger neighbouring powers. A socio-economic history must therefore distinguish political command from the underlying systems that sustained it. Agrarian production remained fundamental; villages, market places, artisans, scribes, religious establishments and learned households connected local resources to courts and regional routes. This chapter reads inscriptions, juristic and literary texts, genealogical materials, archaeology and later historiography together, while refusing to turn prescriptive texts into demographic statistics or later caste labels into medieval facts.

33.1 Two dynastic phases, not two sealed economies

Karnata and Oiniwar rule should not be imagined as two self-contained economic systems. A dynasty could change rapidly while fields, irrigation habits, village boundaries, kinship obligations, market routines and craft knowledge continued. Conversely, continuity at village level did not mean political stasis: the destination of revenue, the composition of courts, the scale of fortification and the geography of patronage could alter significantly. The most useful comparison therefore separates layers. At the top were rulers, military retainers, ministers and fiscal claims. Beneath them were landed rights, cultivating households and service relationships. Alongside these stood market exchange, routes toward Nepal and Bengal, religious establishments and scholarly networks. The 1324 conquest is consequently treated below as a major political rupture whose economic effects must be demonstrated sector by sector rather than assumed. This layered method also prevents later Oiniwar institutions from being projected backward into the full Karnata period.

33.2 The source base and its asymmetries

The evidence is uneven. Inscriptions can identify rulers, donors, officials, religious foundations and particular grants, but they illuminate exceptional recorded transactions more readily than ordinary cultivation. Jyotirīśvara's *Varṇaratnākara* provides an extraordinarily rich lexicon of social types, occupations, spaces, commodities and cultural practices, yet its literary form warns against reading every list as a census. Caṇḍeśvara Ṭhakkura's legal and political digests reveal categories through which learned elites thought about property, kingship, taxation, offices and disputes. Genealogies preserve remembered relations among selected groups but are not a universal population register. Archaeology at Simraungadh and associated sites supplies evidence of urban form, art production and material culture. Fifteenth-century works associated with the later Vidyāpati Ṭhakkura illuminate documentary and courtly practices in the Oiniwar world. Each source therefore answers a different question, and secure reconstruction depends on agreement across unlike evidence.

33.3 A Himalayan–Gangetic regional economy

Mithila's economy was shaped by location. The plains between the Himalayan piedmont and the Ganges combined fertile alluvium with rivers whose shifting channels could enrich fields, obstruct movement and destroy settlements. The northern route system connected the plains with Nepal's valleys and passes;

eastward connections led toward Bengal; southward movement reached the Ganges and the wider commercial world of Bihar. Political boundaries did not seal these corridors. People, animals, salt, metals, textiles, manuscripts, ritual specialists and information could move across them at different scales. Simraungadh's position near the modern India–Nepal border makes sense within this geography: it was not a peripheral fortress in national terms that did not yet exist, but a node in a trans-Himalayan and Gangetic landscape. The same geography later allowed Oiniwar courts and learned households to survive through dispersed connections even when political authority became more fragmented.

33.4 Karnata state formation and Simraungadh

The inscriptional date associated with Nanyadeva's establishment of power in 1097 anchors the beginning of Karnata rule more securely than many narrative traditions. Simraungadh became the principal fortified centre of the dynasty. Fortification itself is economic evidence: walls, gates, reservoirs, roads, temples and court buildings required organised labour, materials and recurring provisioning. A capital concentrated consumers who did not produce all of their own food—rulers, soldiers, priests, scribes, artisans, visitors and dependants—and therefore drew surplus from a wider hinterland. Excavated and documented sculpture from the Simraungadh region also points to workshops and patronage connected with broader Pala-Sena artistic currents. Yet the capital should not be equated with the whole economy. Its capacity to function depended on networks of villages, local officials, routes and producers extending well beyond the fortifications.

Karnata to Oiniwar: periodisation without assuming economic rupture

Analytical rule: dynastic change can alter political extraction and patronage while villages, routes, skills and institutions persist.

Figure 128 — Karnata to Oiniwar: political periodisation and economic continuity

33.5 Agriculture as the fiscal foundation

Agriculture was the basic source of reproducible surplus. Medieval textual descriptions of Mithila repeatedly assume a countryside of cultivated fields, cattle, grain, fruit, ponds and village production. The state's interest in land was consequently not abstract territorial possession but access to recurring agrarian resources. Harvest shares, dues, service obligations and rights assigned through grants could support courts and institutions without requiring all produce to be physically transported to a central treasury. The ecological regime demanded flexibility: floods, silt deposition and channel migration could alter productivity over short distances, while the dense river network created both risk and opportunity. A realistic political

economy must therefore avoid imagining uniform yields or a single tax rate across the region. What can be stated securely is that control over agrarian claims—who could demand, remit, receive or transfer them—was central to both royal authority and local social power.

33.6 Land grants and layered rights

A medieval grant did not necessarily transfer modern absolute ownership. Charters and legal texts could distinguish cultivated land, waste, water, trees, fiscal dues and jurisdictional privileges, while existing cultivators might continue working the soil after a superior right changed hands. The useful question is therefore which rights were transferred: revenue, possession, exemption, adjudicatory privilege, access to produce or some combination. Grants to Brahmanas and religious establishments could create durable local interests and tie scholarly or ritual service to agrarian resources. They could also encourage settlement and reclamation, though such effects must be established case by case. Because many surviving grants record privileged transactions, they over-represent recipients capable of preserving documents. They nonetheless show the mechanism by which political power became embedded in local society: royal favour could be translated into recurrent claims on land and labour.

33.7 Cultivators, tenants and the production of surplus

The archive is much less articulate about ordinary cultivators than about kings and learned recipients, but no landed order functioned without them. Peasant households supplied grain, maintained cattle, processed produce and absorbed ecological shocks. Depending on locality and tenure, they might owe shares, fixed dues, labour or payments in kind and cash. C. P. N. Sinha's reconstruction of Karnata social and economic life drew attention to literary evidence for unequal relations between producing households and those claiming surplus. Such evidence should be used to identify hierarchy, not to invent precise rates of exploitation. Cultivators were also not a homogeneous class: access to plough animals, family labour, irrigable or high land, market connections and local protection could differentiate households substantially. The village economy was thus a field of negotiation among producers, superior claimants, service groups and officials rather than a simple two-class structure.

33.8 Floodplain ecology and economic resilience

The Kosi, Kamla, Bagmati, Gandak systems and their tributaries made northern Mithila unusually dynamic. Medieval people lacked modern embankment regimes, but they possessed local knowledge of raised settlement sites, seasonal routes, ponds, channels and crop timing. Floods could destroy standing crops and houses while also renewing soils and creating fisheries and grazing zones. The political economy therefore had to accommodate uncertainty. A revenue demand that ignored local ecological variation could undermine its own base, whereas flexible assessment, remission or dispersed storage could make extraction more sustainable. Direct documentation for such administrative responses is incomplete, so the chapter does not claim a uniform Karnata or Oiniwar flood policy. Instead, ecology is treated as a structural constraint explaining why settlement, market access and household reserves mattered as much as nominal sovereignty.

33.9 Village, market and town as connected scales

The categories 'village', 'market' and 'town' were not isolated boxes. A large village could host periodic exchange, specialised artisans and religious establishments; a market could serve several villages without becoming a permanent urban centre; a capital such as Simraungadh depended on supplies assembled through smaller nodes. Jyotirīśvara's descriptive vocabulary is valuable precisely because it presents a socially

differentiated world of streets, shops, occupations, entertainments and goods alongside rural life. Exchange linked grain producers with oil pressers, potters, metalworkers, cloth makers, transporters and merchants. Periodic markets reduced the need for continuous urban residence and fit a floodplain landscape in which movement could be seasonal. Under the Oiniwars, the importance of multiple smaller court locations reinforces the likelihood that political consumption was distributed across a network rather than concentrated permanently in one metropolis.

33.10 Craft production and specialised labour

Courtly and religious consumption stimulated specialised work. Stone carving, metalwork, carpentry, pottery, textiles, manuscript preparation, construction and ornament production are visible directly or indirectly in the material and textual record. Simraungadh sculpture demonstrates that skilled artistic production participated in interregional styles while remaining locally embedded. Craft specialists could work for patrons without being permanently attached to a single court; some skills were mobile, and commissions could draw artisans between centres. Everyday craft production was even broader, serving agricultural households with tools, vessels, clothing and building materials. The surviving prestige objects must therefore not define the whole craft economy. They are best understood as the upper end of a larger occupational spectrum in which subsistence, market demand, temple requirements and elite patronage overlapped.

33.11 Trade routes, tolls and cross-border exchange

The Karnata capital's northern position placed it close to routes between the Gangetic plain and Nepal. Later political and literary evidence likewise shows Mithila embedded among Nepal, Bengal, Jaunpur and the Delhi sphere. Long-distance commerce did not displace local exchange; it added higher-value goods and opportunities for tolls, brokerage, transport and credit. Salt from Himalayan or trans-Himalayan circuits, metal, horses, textiles and luxury goods could move through regional networks, while grain and bulky produce generally travelled shorter distances unless price differentials justified transport. Evidence is insufficient to quantify trade volumes. Nevertheless, repeated political interest in routes and frontier centres indicates that connectivity itself was a resource. Control of passage, market dues and secure transit could generate income while also making courts dependent on wider geopolitical stability.

33.12 Money, payments in kind and the limits of monetisation claims

Coins circulated in the wider north Indian economy, but the presence of money does not imply that every tax, wage or transaction was monetised. Agrarian dues could be collected in produce; services could be remunerated through assignments, shares, customary perquisites or gifts; market transactions could use coin selectively. Political change also brought different monetary zones into contact. For social history the key issue is plural payment. Households and institutions could combine grain, labour, land rights, cash and ceremonial gifts. This plurality gave resilience where coin supply was thin but also made obligations difficult to compare. Because the surviving evidence does not support a continuous price series for medieval Mithila, claims about inflation or total monetisation would be speculative. The chapter therefore treats money as one instrument inside a mixed economy rather than as a measure of economic modernity.

Agrarian surplus circulated through several institutions

The figure is a flow model, not a claim that every payment passed through a single treasury.

Figure 129 — Agrarian surplus circulated through courts, markets, services and learned institutions

33.13 Religious and learned institutions as economic actors

Temples, monasteries and learned households consumed resources, employed specialists and redistributed patronage. A grant could sustain ritual, teaching, manuscript work, maintenance of buildings or hospitality. The Naulagarh inscriptional evidence associated with the Karnata world also complicates any image of a single religious economy by preserving traces of Buddhist institutional presence alongside Brahmanical patronage. Intellectual centres required food, housing and material support just as courts did. Their economic importance lay not only in landholding but in creating demand for scribes, students, ritual goods, books and travel. At the same time, religious prestige could legitimate donors and help stabilise claims to local authority. It is therefore misleading to separate ‘culture’ from ‘economy’: patronage converted agrarian surplus into institutions whose symbolic capital could strengthen political and social relationships.

33.14 Administrative labour: ministers, scribes and record specialists

Government required literate labour. Inscriptions name ministers and officials; legal digests presume adjudication and record; grants themselves required drafting, authentication and preservation. Kayastha and other scribal lineages appear in the documentary landscape, but the terminology must be read historically rather than forced into later fixed caste taxonomies. The career of Śrīdharadāsa, known from inscriptional and literary contexts, illustrates how a skilled official could connect courts and regions. Administrative expertise was portable capital: knowledge of formulae, account keeping, correspondence and precedent could survive dynastic change better than a particular ruler’s household. Such specialists formed an important bridge between abstract sovereignty and the practical extraction or allocation of resources. Their work made land claims legible and helped convert oral agreements into documents capable of outliving the immediate transaction.

33.15 Nanyadeva’s court: patronage as economic concentration

Nanyadeva is remembered not only as a conqueror but as a patron and intellectual participant, including in musical scholarship. Courtly learning was financed activity. Musicians, teachers, scribes, ritual specialists and performers needed maintenance, while prestige objects and ceremonies mobilised artisans and suppliers.

Patronage could attract skilled people to a court and give the dynasty cultural authority beyond military success. The economic significance of such patronage is not that culture formed a separate luxury sector, but that it concentrated surplus into human capital and reputation. A court that rewarded learning could create networks whose members later served other rulers. This helps explain why intellectual traditions in Mithila survived political disruptions. Yet patronage was selective: its visibility in texts reflects elite priorities and cannot be taken as evidence that prosperity was evenly distributed among rural producers.

33.16 Jyotirīśvara's Varṇaratnākara as an economic archive

The Varṇaratnākara, associated with the Karnata-period milieu, is one of the richest sources for reconstructing the texture of social life. Its catalogues evoke towns, markets, occupations, foodstuffs, ornaments, entertainments, religious specialists, courtesans, travellers and many forms of material culture. For economic history its value lies in range: it demonstrates a vocabulary capable of distinguishing numerous kinds of work and consumption. But genre matters. A literary thesaurus arranges the world rhetorically; it does not report numbers employed in each occupation or the market share of a commodity. The safest use is relational. If a text distinguishes many service and craft roles, historians can infer occupational specialisation; if it names diverse goods and spaces, they can infer differentiated consumption and exchange. Quantification, however, requires evidence the text was never designed to provide.

33.17 Harisimhadeva, genealogy and regulated alliance

Tradition associates Harisimhadeva's reign with the formalisation or strengthening of genealogical regulation later embodied in the Panji system. Chapter 31 treated that tradition critically: surviving manuscripts and later accounts must be dated, and institutional development may have occurred in stages. Economically, regulated marriage among selected lineages could shape alliance, property strategy, professional reputation and access to patronage. Genealogical expertise itself became specialised service. Yet this cannot justify projecting all later social rankings backward into the early fourteenth century. In particular, the distinct Śrotiṛya sub-caste classification adopted in this project is dated from Panji evidence to around 1800 CE, not to the Karnata court. Medieval records may preserve learned lineages and status distinctions without proving the existence of the later sub-caste as a fixed category.

33.18 The conquest of 1324: a political rupture with uneven economic effects

Ghiyasuddin Tughluq's campaign ended the Karnata court at Simraungadh and displaced Harisimhadeva toward Nepal. For political history this is a clear rupture. For social economy, the consequences were differentiated. A royal establishment could be dispersed; officers could lose assignments; military demands and routes could shift; elite patrons could relocate. Yet cultivated fields, village communities, craft knowledge and local kinship networks did not vanish automatically. Some disruption was likely around military movement and the abandoned court, but a claim of region-wide economic collapse would require evidence not presently available. The correct model is selective destruction and reorientation within a resilient agrarian landscape. This distinction also clarifies why new political arrangements could emerge relatively quickly: successor rulers inherited not empty territory but functioning productive and social infrastructures.

1324: separating political rupture from socio-economic continuity

Historical reconstruction requires evidence for each layer; “conquest” is not a synonym for total economic collapse.

Figure 130 — The 1324 rupture: separating political change from socio-economic persistence

33.19 Continuity under new overlords

After the Karnata collapse, Mithila’s rulers operated in a world where Delhi, Bengal, Jaunpur and Nepal could exert varying degrees of pressure or opportunity. Political autonomy was therefore negotiated rather than absolute. Tribute, military service, recognition and alliance could redirect part of the surplus outward while leaving much local administration in place. Such arrangements were common in premodern South Asia because central powers often found it cheaper to work through local intermediaries than to administer every village directly. The resulting economy had several levels of claim: cultivators produced; local holders and officials collected or managed; a regional court supported its household and dependants; and an overlord could demand acknowledgement or tribute. This layering helps explain why literary culture could flourish in modest courts that were politically subordinate yet socially influential.

33.20 Oiniwar polity and the scale of court power

The Oiniwars did not reproduce Simraungadh’s large fortified capital. Their political centres shifted among places remembered as Oini, Sugauna, Devakuli, Gajarathpura and other court locations. Pankaj Jha’s study of the fifteenth-century literary world emphasises the relatively small scale and contingent autonomy of these north Bihar chieftaincies. Economically, a smaller court could still be significant locally. It concentrated revenue, consumed agricultural produce, commissioned texts and rituals, supported officials and formed alliances. But its fiscal reach may have been more negotiated and spatially dispersed than that of an idealised centralised kingdom. The movement of court centres also redistributed demand: villages near a residence could gain patrons and suppliers, while old centres could decline. Court mobility should therefore be read as a feature of regional political economy, not simply as evidence of administrative weakness.

33.21 Shifting capitals and distributed fiscal geography

A moving or multiple court changes the geography of extraction and consumption. Instead of one permanent urban concentration, authority travels with the ruler, household, officers and ritual apparatus. Supplies may be assembled from nearby estates and villages; temporary markets and service clusters can expand around the court; routes between residences gain importance. Oiniwar political geography therefore

suggests a network of nodes rather than a single dominant city. This does not mean taxes were improvised at every move. Documentary claims, hereditary rights and local intermediaries could maintain continuity while the court relocated. The economic effect was to bind several localities into circuits of hospitality, provisioning and patronage. It also reduced the historian's ability to identify one archaeological 'capital' whose material record would stand for the whole dynasty.

33.22 Learned households and the political economy of scholarship

Mithila's reputation as a centre of Sanskrit learning in the fourteenth to sixteenth centuries rested on material support. Scholars required households, students, manuscripts, food and time removed from full-time agricultural labour. Land assignments, gifts, court employment, ritual fees and teaching networks could supply these resources. Learning in turn generated political value: jurists advised rulers, scribes prepared documents, teachers enhanced a patron's reputation and scholastic lineages attracted students from outside the region. Knowledge was therefore both cultural capital and a form of skilled labour. The Oiniwar court's modest territorial scale did not prevent it from participating in much larger intellectual networks. Indeed, portable expertise allowed a learned household to remain influential even when a particular patron declined. This institutional resilience is one reason political fragmentation should not be equated with cultural or economic stagnation.

33.23 Caṇḍeśvara and the fiscal imagination of kingship

Caṇḍeśvara Ṭhakkura's Rājanīratnākara belongs to the early fourteenth-century Mithila intellectual world and systematises political categories drawn from earlier Sanskrit traditions. As a normative treatise it cannot be used as an administrative manual proving that every rule was implemented. It nevertheless reveals what a learned minister-jurist considered essential to kingship: revenue, officers, protection, punishment, territory, war, counsel and legitimate transfer of authority. Read alongside his legal digests, the work demonstrates a sophisticated conceptual separation of fiscal and judicial problems. This matters economically because extraction required legitimacy and procedure as well as force. The treatise's afterlife also shows how regional political actors could appropriate older imperial vocabularies even when ruling much smaller territories. Political imagination could be larger than the material scale of a court.

33.24 Document culture and the later Vidyāpati Ṭhakkura

The project distinguishes the earlier Mahākavi Vidyāpati from the later Vidyāpati Ṭhakkura associated with Oiniwar and neighbouring courts and with Sanskrit and Avahatṭa works such as Likhanāvalī, Puruṣaparīkṣā and Kīrtilatā. For Chapter 33, Likhanāvalī is especially important because a manual of letters and documents reveals the social demand for formal written communication. Petitions, orders, grants, acknowledgements and private letters required recognised forms, scribal skill and institutional memory. Pankaj Jha has shown that such writing practices were part of a broader fifteenth-century political culture rather than mere literary ornament. Economically, documentation reduced ambiguity in obligations and allowed claims to travel across space and time. It also created specialised labour and gave literate households leverage in courts and disputes.

Oiniwar-era court society as a distributed network

"Distributed" describes multiple interacting centres and households; it does not imply absence of hierarchy.

Figure 131 — Oiniwar-era court society as a distributed social-economic network

33.25 Service communities and occupational interdependence

Agrarian surplus supported a wide field of service labour: artisans, transporters, ritual specialists, domestic workers, performers, guards, messengers, scribes and many other occupations. Some services were exchanged through markets; others were embedded in patronage, customary dues or household dependency. The temptation to translate each medieval occupational term directly into a later caste is especially dangerous. Occupation, lineage, status and endogamy could overlap without being identical, and their relationship changed over centuries. The evidence from literary lists and legal categories is strongest for demonstrating occupational differentiation and hierarchy. It is weaker for proving the exact social boundaries of every group. A social-economic history should therefore ask what work was performed, who paid or maintained the worker, and how portable the skill was before assigning a later community label.

33.26 Women and household production

Chapter 32 showed that women's legal visibility is only one part of their economic history. In the Karnata and Oiniwar countryside, household production depended on labour that texts often leave unnamed: processing grain, managing food stores, textile work, tending animals, collecting fuel, assisting cultivation, caring for children and maintaining ritual and domestic spaces. Elite households added management of servants, gifts and movable property. Marriage linked households and could redirect resources through dowry-like transfers, *strīdhana*, maintenance and inheritance claims, but the surviving prescriptive texts cannot tell us how frequently each rule was applied across social strata. The important economic conclusion is structural: the agrarian household was not a male individual producer. It was a cooperative and hierarchical unit whose reproduction depended heavily on women's paid and unpaid work, even where formal documents foreground male holders.

33.27 Mobility, military labour and migration

Political competition generated movement. Soldiers, retainers, messengers, scribes, scholars and artisans could follow patrons; merchants and transporters followed opportunity; displaced elites crossed into Nepal after military defeat. Such mobility moved more than people. It carried languages, legal forms, artistic styles,

religious practices and credit relationships. The Karnata dynasty's own origin traditions place it within wider movements of military elites, while the post-1324 displacement of Harisimhadeva illustrates the reverse process. Later Oiniwar politics also unfolded amid shifting relations with neighbouring sultanates. Mobility therefore belongs inside economic history because skills and patronage were transferable assets. At the same time, migration should not be exaggerated into mass demographic replacement without evidence. Most agrarian production depended on populations that remained tied to local land and water regimes even as elites circulated.

33.28 Regional powers and the circulation of surplus

Mithila's economy was never insulated from larger states. Karnata rulers negotiated with Senas, Kalachuris and powers in Nepal; later chieftains confronted Delhi, Bengal and Jaunpur. Warfare could destroy assets, but political connection also opened markets and patronage. A ruler recognised by a larger power might retain local revenues after tribute; a scholar could seek service beyond Mithila; merchants could exploit routes protected by changing authorities. The fifteenth-century world described by later Vidyapati Thakkura's political literature makes sense in this multi-centred environment. Regional surplus thus circulated outward through tribute, military expenditure and trade while external goods, coin, styles and ideas circulated inward. The balance varied over time, and the evidence does not permit a single estimate of 'drain' or prosperity. What is clear is that political economy operated across scales larger than the local dynasty.

33.29 Status formation without retrospective caste projection

Land, office, learning, ritual authority and marriage regulation could generate durable status differences. Medieval Mithila unquestionably contained hierarchy and named social groups. The methodological problem is not whether hierarchy existed but how its categories changed. Later genealogies and colonial ethnographies often present classifications as timeless, whereas earlier inscriptions and texts may use different vocabularies or attach different meanings to the same word. This chapter therefore follows the governing rule established in Chapters 29–31: no modern or early-modern sub-caste will be projected backward without period evidence. The Śrottriya case is decisive. Panji-based evidence used in this project dates its emergence as a distinct sub-caste to around 1800 CE. Karnata or Oiniwar learned elites can be described as Brahmanas, jurists, scholars or holders where sources support those terms, but not retrospectively as members of that later fixed sub-caste.

33.30 Conclusion: prosperity, dynastic change and institutional continuity

Royal patronage, rich literary description, monumental remains and active scholarship can tempt historians to label an entire period prosperous. Such a judgement requires caution. Courtly abundance may coexist with heavy peasant burdens; an urban centre may flourish while flood-affected districts struggle; elite texts may celebrate gifts precisely because resources were concentrated. Conversely, political fragmentation does not prove economic decline if cultivation, markets and skilled labour continue. The evidence supports a picture of productive agrarian foundations, occupational differentiation, regional trade and substantial patronage under both Karnata and Oiniwar orders. It does not support a numerical estimate of regional income or a uniform standard of living. Prosperity is therefore treated as distributional and sectoral: who controlled surplus, who consumed it, and which institutions were able to reproduce themselves across political change.

The Karnata and Oiniwar centuries reveal a political economy in which land remained fundamental but never acted alone. Agrarian surplus moved through villages, offices, courts, religious establishments, learned households, markets and long-distance routes. Simraungadh represented one powerful concentration of that system; its fall in 1324 altered the political centre without erasing the productive landscape. Oiniwar rule reorganised authority around smaller and shifting courts, while documentary expertise, Sanskrit learning, genealogical practice and regional mobility supplied forms of continuity. The later Vidyāpati Ṭhakkura's documentary and political works belong to this fifteenth-century world and must remain distinct from the earlier Mahākavi Vidyāpati. Likewise, later caste formations must not be made medieval by repetition. The central historical lesson is institutional: dynasties command attention because their names survive, but social economies endure through the households, skills, documents, land rights and routes that make rule possible.

Table 33.1 — Karnata and Oiniwar social economy: evidence, use and limit

Evidence	Primary period / context	Secure use	Limit
Karnata inscriptions and grants	12th–early 14th c.	Identify rulers, officials, donors, institutions and recorded rights	Recorded grants over-represent privileged transactions and recipients
Simraungadh archaeology and sculpture	Karnata capital and wider artistic zone	Reconstruct fortified consumption, skilled production and material connections	Capital evidence cannot represent every village economy
Jyotirīśvara, Varṇaratnākara	Late Karnata milieu	Recover vocabulary of occupations, goods, spaces and consumption	Literary classification is not a census or price series
Caṇḍeśvara's legal and political digests	Early 14th c.	Study learned concepts of property, revenue, office and governance	Normative categories do not prove universal administrative practice
Panji and genealogical materials	Developing medieval tradition with later manuscripts	Trace selected marriage, lineage and professional networks when dated	Not a universal population register; later categories require independent dating
Later Vidyāpati Ṭhakkura's works	15th-century Oiniwar / neighbouring courts	Study documentary practice, political language, mobility and courtly networks	Literary-political works require genre control and must not be assigned to the earlier Mahākavi
Regional chronicles and later histories	Post-medieval witnesses to earlier traditions	Recover remembered political sequences and compare source traditions	Late testimony can compress chronology and project later institutions backward
Environmental and settlement evidence	Long-duration floodplain economy	Explain constraints on agriculture, routes, storage and settlement resilience	Does not by itself establish a particular tax or social rule

Chapter 34 — Islam, Migration and New Social Worlds

Islam entered the social history of Mithila, Vajji and Anga through more than conquest. From the thirteenth century onward, the region stood inside a widening field of movement linking Delhi and the middle Ganga plain, Lakhnauti and Bengal, Jaunpur, Bihar, Anga and the routes toward Nepal. Armies and governors mattered, but so did merchants, transporters, scribes, scholars, Sufis, artisans, soldiers seeking employment, refugees and households that moved with patrons or opportunity. Their presence created new institutions and new forms of language, consumption and association without making every locality identical. The history of these encounters therefore has to be reconstructed as a history of mobility and settlement rather than as a simple sequence of invasions. The chapter also keeps four processes analytically distinct: conquest, migration, durable settlement and religious change. A victorious army does not by itself prove large-scale migration; a migrant population does not by itself prove conversion among older inhabitants; and later demographic patterns cannot be projected backward without evidence. Persian chronicles, Arabic and Persian inscriptions, Sufi letters and discourses, Sanskrit and Avahatṭa literature, archaeology, genealogy and later regional histories each preserve different slices of this past. Read together and critically, they reveal a medieval society in which religious difference existed alongside political bargaining, service, exchange, shared routes and multilingual communication.

34.1 Islam as a social history, not an invasion label

The conventional phrase ‘Muslim invasion’ can identify episodes of warfare but is too narrow to explain social change. Political armies were composed of people with different origins and functions; after campaigns, some individuals departed, some entered garrisons or service, and others were followed by administrators, scholars, traders and religious specialists. At the same time, older residents continued to cultivate land, manage villages, worship, trade and serve local courts. Islam therefore appeared in the region through institutions and persons whose relations to state power varied greatly. A qazi, a mounted soldier, a Sufi teacher, a merchant and a Persian-trained scribe did not represent a single social type. Nor did Muslim communities remain socially homogeneous after settlement. The correct historical question is not when an abstract ‘Islam’ arrived, but how particular people, practices and institutions acquired local presence. This approach also prevents political chronology from swallowing social chronology: the dates of conquest provide anchors, while the density and character of everyday interaction must be established separately.

34.2 Source control: chronicles, inscriptions, literature and memory

The evidence is uneven and socially selective. Sultanate chronicles privilege rulers, campaigns, rebellions and elite appointments. Arabic and Persian inscriptions are often more securely dated and can establish the presence of mosques, tombs, patrons, builders and officials, but their survival is accidental and geographically uneven. Sufi maktubat and malfuzat illuminate teaching networks, disciples and ethical worlds, yet they are not censuses of Muslim settlement. Sanskrit and Avahatṭa texts composed in Mithila can preserve political vocabulary, descriptions of outsiders, documentary forms and memories of conflict, but literary genre shapes what they say. Later genealogies and local histories may preserve earlier traditions while also reorganising them through later social categories. No single class of evidence can sustain a demographic narrative. The method used here is cumulative: a claim becomes stronger when independent evidence—dated inscription, contemporary or near-contemporary text, material remain and regionally plausible route—converges, and weaker when it depends only on a much later story.

34.3 Before 1324: a connected frontier already in formation

The Tughluq attack on Simraungadh in 1324 was a major political rupture, but it was not the beginning of all contact between Mithila and Muslim-ruled territories. By the thirteenth century, Turkish and Persianate states were established across much of the Gangetic plain and Bengal. Routes joining Bihar, Lakhnauti, the Ganga crossings and north Bihar carried military information, merchants, messengers and officials. Political pressure from neighbouring regimes could be episodic rather than continuous, and frontier zones could shift without permanent occupation. The very existence of a Karnata court in a region surrounded by expanding Sultanate power created diplomatic and military contact before direct conquest. Evidence for particular settlements in Mithila before 1324 must nevertheless be treated case by case. The broader connection is historically secure; the size and permanence of every local Muslim presence are not. This distinction matters because later narratives sometimes convert repeated border contact into anachronistic claims of uniform rule.

34.4 The 1324 Tughluq attack: political rupture, not demographic zero point

Ghiyasuddin Tughluq's 1324 campaign against Simraungadh ended the Karnata court and forced Harisimhadeva northward. Persian and regional traditions differ in narrative detail, but the political consequence is clear: the fortified centre ceased to function as the dynastic capital. For social history, the event should be disaggregated. A campaign could destroy or appropriate stores, disrupt routes, displace retainers and redirect tribute. It could also bring soldiers, camp followers, officials and intermediaries into new landscapes. Yet even a successful conquest did not empty the countryside or automatically replace its population. Village cultivation, kinship and local exchange could survive while political command changed. Nor does the presence of a Sultanate army prove the immediate creation of large Muslim settlements throughout Tirhut. The event is best treated as an accelerator of mobility and political connection, one that widened the channels through which later service, settlement and cultural contact operated.

Mithila and the wider north-eastern Gangetic world, c. 1200-1550

Political interventions changed courts and routes; social change accumulated through repeated mobility, settlement and exchange.

Figure 132 — Political contact and social change, c. 1200–1550

34.5 Tirhut between Delhi, Bengal and Jaunpur

After the Karnata collapse, Tirhut lay among several centres of power whose reach fluctuated. Delhi's Tughluqs claimed authority; Bengal sultans repeatedly influenced Bihar; the Sharqi kingdom of Jaunpur became a major fifteenth-century power; and local Oiniwar rulers retained or recovered varying degrees of autonomy. Political maps that colour an entire region as permanently belonging to one state conceal this instability. For inhabitants, overlapping claims could mean tribute to one power at one moment, alliance with another at the next, and substantial local autonomy in between. Such a setting favoured intermediaries who could negotiate languages, legal conventions and political expectations. It also encouraged movement of military specialists, envoys and scribes across boundaries that were political rather than modern territorial borders. Social change followed these repeated contacts more than any single line of conquest.

34.6 Military mobility and the social life of garrisons

Armies were mobile labour systems. Cavalrymen, foot soldiers, armourers, farriers, suppliers, cooks, transport workers, clerks and camp merchants moved with campaigns. Where military presence became recurrent, some of these people could remain in service under provincial or local authorities, marry, acquire property or develop supply relations with nearby markets. Garrisons therefore mattered socially even when they were small. Their demand for grain, fodder, animals, metalwork, cloth and transport linked military power to rural producers and artisans. At the same time, the archaeological or textual visibility of a fort should not be converted into an estimate of population without evidence. The key transformation was the creation of recurring service corridors: military employment became one route by which people from Persianate and Islamicate networks entered north Bihar, while local men could also seek employment in larger armies. Movement was two-way, not simply an influx from outside.

34.7 Administrators, qazis and fiscal intermediaries

Sultanate expansion depended on literate administration as well as force. Revenue assessment, orders, petitions, judicial decisions and correspondence required trained personnel. Persian became increasingly important in political and documentary worlds across north India, while Arabic retained high prestige in religious and legal learning. In frontier and tributary regions, officials often depended on local intermediaries who knew land, kinship, routes and customary obligations. This produced a social field in which political authority was translated through collaboration. A Persian document did not mean that the countryside had become Persian-speaking; rather, it indicates an administrative register with specialised users. Likewise, the existence of a qazi establishes an Islamic legal office but not the disappearance of other forums of dispute settlement. Multiple normative and documentary systems could coexist, each serving different communities or types of claim.

34.8 Migration was socially differentiated

Migration should not be treated as a single stream. Some movement was elite and temporary: ambassadors, officers and scholars followed courts. Some was occupational: horse dealers, merchants, artisans, scribes and soldiers followed demand. Some was devotional: Sufis and students travelled between teachers, hospices and centres of learning. Some was coerced or crisis-driven: war and dynastic collapse displaced retainers and households. Still other movement involved local people leaving Mithila for Bengal, Jaunpur, Bihar or Nepal. These migrants differed in resources and in their ability to preserve networks across distance. A high-ranking officer could travel with dependants and patronage; a transporter or craft worker might attach himself to a market or military route; a displaced cultivator left far fewer records. The archive

therefore magnifies mobile elites while under-recording ordinary circulation. Social history must compensate by distinguishing visibility from numerical importance.

Migration and circulation around medieval Tirhut/Mithila

Figure 133 — Bidirectional migration and circulation around medieval Tirhut/Mithila

34.9 Markets, merchants and the Ganga–Bengal corridor

Commercial movement linked Mithila to the Ganga and to eastern markets regardless of dynastic allegiance. Grain, salt, cloth, livestock, metals, horses and specialised goods travelled through combinations of river, road and periodic market. Anga and the Bhagalpur–Munger zone connected the middle and lower Ganga worlds, while crossings toward Hajipur and other north-Bihar routes linked Tirhut to wider circuits. Muslim merchants were part of these networks, but commerce should not be assigned a single religious identity: Hindu, Jain and Muslim traders, transporters and brokers could use the same routes and market infrastructure. Commercial contact created practical multilingualism and repeated face-to-face interaction. It also carried objects, measures, fashions and credit practices beyond the political centres where chronicles concentrate attention. The result was not cultural uniformity but increasing familiarity across social boundaries.

34.10 Sufi mobility and the geography of discipleship

Sufi networks offer a different map from political conquest. Teachers travelled, disciples visited, letters circulated, and lodges or hospices connected local religious life to wider spiritual lineages. The fourteenth-century career of Sharafuddin Ahmad Yahya Maneri in Bihar is particularly important for understanding the eastern Gangetic environment, even though Bihar Sharif and Maner are not themselves Mithila. His Hundred Letters and associated traditions show a Persianate Islamic learned and devotional world rooted in Bihar and connected to patrons, disciples and other centres. Such evidence makes the presence of mobile religious networks near Mithila historically plausible and helps explain how Islam could spread through teaching and association independently of direct state policy. It does not, however, license the assignment of every later shrine or conversion story to the fourteenth century. Each local tradition requires its own dating.

34.11 Bihar's Sufi centres and Mithila: proximity without conflation

The major documented Sufi centres of medieval Bihar demonstrate a dense religious landscape south of the Ganga and along important routes. Their influence could reach northward through disciples, correspondence, pilgrimage and patronage. Yet regional proximity must not be confused with direct evidence for institutional branches in every part of Mithila. A careful history therefore uses Maneri and other Bihar Sufis as evidence for the wider social world in which Tirhut participated, while reserving claims about particular Mithila shrines for locally dated sources. This is especially important because later hagiography often telescopes centuries and links prestigious saints to places in ways that enhance local sanctity. Hagiographic memory is historically valuable—it reveals how communities understood belonging—but it must be separated from the chronology of initial settlement.

34.12 Mosques, tombs and inscriptions: material anchors with survival bias

Arabic and Persian inscriptions are among the strongest chronological anchors for Muslim institutions in Bihar. A dated foundation or funerary inscription can identify a patron, office, ruler, building and religious vocabulary at a particular place. Qeyamuddin Ahmad's corpus demonstrates the variety of such evidence across Bihar under Tughluq, Sharqi, Bengal Sultanate, Afghan and Mughal regimes. For north Bihar, however, survival and publication are uneven. Floods, rebuilding, reuse of stone, changing settlement and inadequate documentation have erased much. Absence of a known inscription therefore cannot prove absence of a community, just as one surviving inscription cannot establish the size of a settlement. Material evidence is best read as a minimum: it proves that a particular institution or person existed where and when the object says, while demographic conclusions require additional evidence.

34.13 Towns and route junctions as zones of intensified encounter

Contact was rarely distributed evenly across the countryside. Administrative centres, ferries, forts, pilgrimage sites, large markets and route junctions concentrated strangers and specialists. A village away from major routes might experience political change mainly through taxation or occasional troop passage; a market town could host merchants, scribes, soldiers, preachers and travellers from several linguistic and religious communities. This unevenness helps explain why cultural borrowing can appear strongly in elite or urban texts while many rural practices remain locally continuous. It also cautions against using the history of one town to represent the whole region. Social worlds overlapped at nodes and then diffused selectively through marriage, employment, patronage and commerce.

34.14 Multilingualism: Persian, Arabic, Sanskrit, Maithili and Avahaṭṭa

The new political environment increased the practical value of multilingual competence. Persian functioned as a major language of power and documentation in Sultanate states; Arabic remained central to Islamic scripture, law and scholarship; Sanskrit continued to dominate learned Brahmanical disciplines in Mithila; and Maithili and related vernacular registers carried everyday and literary communication. Avahaṭṭa and other literary registers could mediate between high and vernacular forms. These languages did not occupy sealed communities. Pankaj Jha's study of fifteenth-century Mithila demonstrates a literary world shaped by interaction among diverse political-cultural traditions. Borrowed terms, comparable administrative genres and shared ethical concerns show contact without requiring that one language simply replaced another. Multilingualism was a social skill and a record of mobility.

34.15 Documentary labour and the translation of authority

Documents connected people who did not share the same oral language or legal tradition. Orders, letters, petitions, grants and acknowledgements had to be drafted in recognised forms, carried, read and interpreted. This created demand for scribes and intermediaries able to move between local knowledge and wider political conventions. The later Vidyāpati Ṭhakkura's *Likhanāvalī* is crucial precisely because it belongs to a fifteenth-century world in which documentary genres had become sophisticated instruments of political and social action. The work is Sanskrit, but its documentary imagination existed alongside Persian epistolary and administrative traditions. Similarity should not be reduced to direct copying without proof; the stronger point is that north Indian courts were converging on the need for portable written forms. Such practices helped migrants and local elites negotiate property, service and patronage across political boundaries.

34.16 The later Vidyāpati Ṭhakkura in a Persianate-connected world

This project keeps the later Vidyāpati Ṭhakkura distinct from the earlier Mahākavi Vidyāpati. The fifteenth-century author associated with Oiniwar and neighbouring courts wrote in Sanskrit and Avahatṭa within a political world already transformed by more than two centuries of Indo-Persian state formation. His *Kīrtilatā* and other works refer to rulers, warfare, political conduct and social types in ways that make sense only inside this connected environment. Pankaj Jha has shown that the author's literary universe was neither culturally isolated nor reducible to Persian influence. It was polycentric and multilingual, capable of appropriating, translating and criticising forms of authority from several traditions. For social history this is evidence that elite intellectuals in Mithila understood and operated within a wider north Indian political ecology.

Channels through which new social worlds formed

Figure 134 — Channels through which new social worlds formed

34.17 *Kīrtilatā*: political contact seen through literary genre

Kīrtilatā is valuable because it records a world of conflict, kingship, travel and political aspiration, but it remains a crafted literary text. Its descriptions of Turks or Sultanate power cannot be read as a statistical account of Muslim society. Literary contrast can sharpen identities for narrative purposes, while praise of a patron can organise events around heroic legitimacy. The text becomes most useful when read alongside

political chronology and documentary evidence. It shows that Muslim rulers and Persianate power were not remote abstractions for fifteenth-century Mithila's courtly imagination. At the same time, its very sophistication demonstrates interaction: an author could represent competing political worlds using a repertoire intelligible to audiences already familiar with them. The source therefore reveals cultural proximity more securely than demographic proportion.

34.18 Local rulers and Sultanate powers: negotiation as normal politics

Relations between Oiniwar rulers and larger Sultanate states were not permanently hostile or permanently subordinate. Tribute, conflict, alliance, recognition and tactical accommodation could succeed one another quickly. A local ruler might resist one expedition while seeking legitimacy or security through another power. This was ordinary medieval politics, not evidence of immutable religious blocs. The social consequence of such negotiation was to keep channels of contact open. Envoys crossed frontiers, gifts circulated, officers changed patrons and military service connected households to distant courts. Political competition could intensify religious rhetoric, but practical governance often required cooperation across religious lines. The historian must therefore separate the ideological language of chronicles from the mixed personnel and negotiated arrangements that made rule workable.

34.19 Conflict and accommodation were simultaneous possibilities

Episodes of violence are indispensable to the history of the period, yet they should not become a total explanation. Raids, sieges and punitive expeditions damaged settlements and created fear; taxation and military extraction could be coercive; sacred sites could be affected by conflict. At the same time, the same political order could employ local landholders, revenue intermediaries, craftsmen and scholars whose religious identities differed from those of ruling elites. Markets reopened after campaigns because all parties required supplies and revenue. Accommodation did not erase inequality or violence, and conflict did not prevent cooperation. Both processes could occur in the same generation. A social history that recognises this simultaneity is better able to explain how durable mixed institutions emerged despite recurrent warfare.

34.20 Conversion: evidence, mechanisms and limits

Religious conversion is the area most vulnerable to retrospective simplification. A political conquest does not demonstrate mass conversion, and a later Muslim-majority village does not prove when or how its ancestors changed affiliation. Conversion could occur through conviction, Sufi teaching, marriage, patronage, occupational networks, household choice or gradual reorientation of ritual practice; the relative importance of these mechanisms varied by place and period. Richard Eaton's work on Bengal is valuable for showing that Islamisation can be connected to long-term agrarian and social processes rather than explained by force alone. Mithila, however, was not Bengal's eastern delta, and Bengal's model cannot be transferred mechanically. For medieval Mithila the surviving evidence supports the existence and growth of Muslim communities more securely than it supports precise conversion rates. Claims about mass coercion or a single conversion mechanism therefore exceed the evidence.

34.21 Household formation, marriage and local rootedness

Migration becomes settlement when people establish durable social reproduction: households, marriage ties, property, neighbourhoods, burial places and institutions. These processes are much less visible than royal campaigns, but they are essential to explaining the persistence of Muslim communities in Bihar and north Bihar. Newcomers could marry within migrant networks or form local alliances; descendants born in

the region no longer fit a simple opposition between ‘foreign’ and ‘indigenous’. Over generations, language, food, dress and occupational practice could become locally specific while religious institutions retained wider connections. The social history of Islam in Mithila is therefore also a history of becoming local. This process did not require cultural sameness. Distinct religious identities could be reproduced within a shared regional economy and vernacular environment.

34.22 Artisans, service groups and occupational neighbourhoods

Courts, military establishments, mosques, shrines and growing markets required specialised labour. Builders, masons, metalworkers, textile producers, leather workers, cooks, grooms, musicians, barbers, boatmen and many other service providers could work for patrons of different religions. Some crafts may have attracted migrants with particular skills, while others remained dominated by established local communities. Occupational proximity created everyday exchange below the level of theological debate. It also complicates later caste narratives: a medieval occupation cannot automatically be equated with a modern caste name or assumed to have had the same boundaries. Muslim occupational communities likewise developed internal distinctions over time. The secure historical point is interdependence: new institutions added demand to an already differentiated labour economy.

34.23 Food, dress and material culture as slow histories of contact

Material culture often changes through borrowing that texts barely notice. New ingredients, cooking methods, tailoring styles, weapons, horse equipment, architectural forms, metal vessels and luxury goods could travel with merchants, soldiers and courts. Persianate elite fashion influenced much of north India, but local climate, agriculture and craft traditions transformed imported forms. It would be misleading to label every later food or garment of north Bihar as ‘Muslim’ or ‘Hindu’ in origin; many items passed through multiple communities before becoming regional. The historical value lies in tracing channels of circulation rather than claiming pure cultural ownership. Archaeology, art history, vocabulary and later culinary traditions can suggest such exchange, but exact medieval dating requires caution. Material hybridity is usually cumulative and difficult to attach to one conquest.

34.24 Shrines, sacred geographies and shared social space

Religious communities maintained doctrinal distinctions, yet sacred landscapes could still overlap socially. Roads to shrines were also market routes; fairs attracted vendors and transporters; saints’ reputations could spread beyond formal discipleship. In many parts of South Asia, later evidence records participation across religious boundaries at particular shrines, but such practices must not automatically be projected into the fourteenth or fifteenth century. The medieval evidence for Mithila is thinner than for some neighbouring regions. What can be stated more securely is that Sufi institutions created new sacred nodes within a landscape already dense with Brahmanical, Buddhist and Jain memories. These nodes participated in the same economy of travel, gift, hospitality and reputation. Religious difference thus produced new places of assembly without making the region a single syncretic culture.

34.25 Muslim society was internally differentiated

The word ‘Muslim’ conceals distinctions of lineage, occupation, wealth, learning, legal status and regional origin. Sultanate elites of Turkish, Afghan, Persian or other backgrounds did not represent all Muslims. Sayyids, learned families, Sufis, soldiers, artisans, converts and rural households could possess very different resources and social claims. Over time, locally born Muslim communities developed hierarchies of their own,

some later expressed through ashraf and occupational status vocabularies. These later classifications should not be projected unchanged into the early medieval period. The same chronological discipline applied elsewhere in this volume therefore applies here: social categories must be dated. Internal Muslim differentiation is historically important because it shaped marriage, patronage and access to office, and because it prevents the false image of two uniform communities confronting one another across a fixed boundary.

34.26 Nepal and the Tarai: bidirectional movement across the northern frontier

The fall of Simraungadh demonstrates dramatically that movement between Mithila and Nepal could accompany political crisis, but migration across the northern frontier was a longer process. Courts, marriage alliances, pilgrimage, trade, scholarship and seasonal movement connected the plains and the Kathmandu Valley. Muslim political expansion in the Gangetic plain added new reasons for mobility without creating a sealed Hindu refuge to the north. Merchants and service personnel could move in either direction, and political refugees from one conflict could become actors in another court. The Tarai's ecology and routes conditioned the scale and seasonality of movement. Because modern international borders did not exist, it is misleading to describe this circulation in present-day immigration terms. It belonged to a regional social world whose political jurisdictions changed more rapidly than many kinship and commercial connections.

34.27 Women, migration and the archive of silence

Medieval sources name far more male rulers, saints, officials and scholars than women, but migration was rarely an exclusively male process. Military and administrative households included dependants; merchants and artisans formed families; elite marriages linked courts; displacement affected women as well as men. Women also transmitted language, food practice, ritual and kinship connections inside households, making them central to the localisation of migrant communities. Yet this work is difficult to document because chronicles rarely record ordinary women and inscriptions tend to privilege patrons. The appropriate response is neither to omit women nor to invent details. Household formation can be inferred as a necessary condition of durable community reproduction, while the specific legal and economic positions of women require evidence of the kind discussed in Chapter 32. The archive's silence is itself a historical fact about whose mobility institutions chose to record.

34.28 Memory, legend and later communal narratives

Later histories of medieval conflict were written in societies with their own religious and political concerns. Local legends may convert an uncertain skirmish into a civilisational battle, assign a shrine to a famous saint, or make a later social division appear ancient. Colonial historiography also encouraged periodisations that treated 'Hindu' and 'Muslim' rule as homogeneous blocks. Such narratives cannot simply be discarded, because they reveal how communities remembered the past, but they require source criticism. Dates, offices, place-names and genealogical sequences should be checked against inscriptions and contemporary texts where possible. The chapter's purpose is not to minimise conflict but to prevent memory from substituting for chronology. Social worlds are especially vulnerable to distortion when later identities are projected backward.

Evidence firewall: four processes that must not be collapsed into one

Figure 135 — Evidence firewall: conquest, migration, settlement and religious change

34.29 What can be inferred securely

Several conclusions are robust. From the thirteenth century onward, Mithila and its neighbouring zones were increasingly connected to Muslim-ruled political and commercial networks. The 1324 Tughluq campaign ended Karnata rule at Simraungadh and intensified political reorientation. Through the fourteenth and fifteenth centuries, Tirhut interacted repeatedly with Delhi, Bengal, Jaunpur and the wider Bihar region. Muslim soldiers, officials, merchants, scholars and religious specialists formed part of these networks, while Sufi institutions in Bihar demonstrate a substantial devotional landscape close to Mithila. Multilingual and documentary interaction is visible in the fifteenth-century intellectual world associated with the later Vidyāpati Thakkura. What cannot yet be measured securely is the size of Muslim populations in particular medieval Mithila localities, the rate of conversion, or the precise date at which many later communities first settled. Those questions require local evidence rather than inference from political maps.

34.30 Conclusion: new social worlds without a single frontier

Islamic presence in medieval Mithila, Vajji and Anga developed through repeated connections rather than one advancing frontier. Conquest opened and redirected political channels, but social worlds were built by people who travelled for service, trade, learning, devotion, marriage and refuge. Their institutions became local through households, markets, documents, shrines and occupational relationships. At the same time, older Sanskrit, vernacular, agrarian and ritual structures remained powerful. The result was neither an untouched pre-Islamic society nor a wholesale cultural replacement. It was a layered region in which political sovereignty, religious affiliation, language and everyday economic cooperation could cut across one another. Recognising those layers makes the history more precise and also prepares the ground for Chapter 35, where Persianate cultural forms can be studied directly without assuming that all Muslim social history was Persianate or that all Persianate influence required Muslim political rule.

The social transformation traced here depended on circulation. Sultanate armies and claims of sovereignty altered the political horizon, but the deeper historical change lay in the multiplication of routes linking courts, markets, shrines, documentary offices and households. Muslim communities in and around Mithila emerged from several streams and acquired local roots over generations. Their histories intersected

with Sanskrit learning, vernacular literary production, agrarian institutions and the regional economies of Bihar, Bengal, Anga and Nepal. The chapter therefore rejects both a conquest-only narrative and an undifferentiated harmony narrative. Conflict, hierarchy, accommodation and borrowing all belonged to the same connected world. Most importantly, conquest, migration, settlement and conversion remain separate evidentiary questions. That distinction allows the medieval record to speak without forcing later demographic or communal categories upon it.

Table 34.1 — Islam, migration and new social worlds: evidence, use and limit

Evidence	What it can establish securely	Best historical use	Limit / caution
Sultanate chronicles and campaign narratives	Named rulers, campaigns, rebellions, political claims and some offices	Anchor political chronology and routes of military intervention	Court-centred; victory claims do not measure settlement or conversion
Arabic and Persian inscriptions	Dated patrons, buildings, tombs, mosques, officials and titlature	Locate specific Muslim institutions and persons in time and place	Survival is uneven; one inscription cannot represent a population
Sufi letters, discourses and hagiography	Teachers, disciples, doctrine, patronage and devotional networks	Reconstruct religious mobility and social connections	Hagiographic layers can be late; not a census of communities
Sanskrit / Avahatṭa texts of Mithila	Political vocabulary, literary representations, documentary genres, elite perceptions	Study multilingual interaction and courtly knowledge	Genre and patronage shape representation; demographic inference is unsafe
Genealogies and later local histories	Remembered lineages, settlement traditions and political sequences	Compare memories with dated evidence and trace later identity formation	Can telescope chronology and project later categories backward
Architecture, archaeology and settlement evidence	Material presence, building practice, route nodes and consumption	Test textual claims and identify durable institutions	Dating may be broad; absence of remains does not prove absence of people
Later demographic and ethnographic records	Distribution of communities in later centuries	Frame questions about continuity that can be tested backward	Cannot by themselves establish medieval origins, dates or conversion mechanisms

Chapter 35 — Persianate Culture and Mithila–Anga

Persianate culture reached Mithila and Anga through administration, courts, Sufi networks, inscriptions, books, routes and material practices rather than through one uniform process. This chapter reconstructs that field without treating “Persianate” as an ethnic identity, without equating it with Islam as a whole, and without assuming that elite documentary change automatically transformed village speech or social life.

35.1 Defining “Persianate” without ethnic or religious conflation

“Persianate” is most useful here as a historical category for a transregional field of language, literary canons, bureaucratic technique, courtly ethics, political imagery, Sufi writing, architecture and social distinction that circulated far beyond Iran. It does not mean that the people participating in that field were ethnically Persian, nor that Persianate culture was identical with Islam. Turkic, Afghan, Indian, Iranian and other elites could share Persian political and literary forms; non-Muslim scribes and scholars could also learn them; and communities using Persianate administrative forms could continue to speak Maithili, eastern Indo-Aryan vernaculars, Sanskrit, Arabic or other languages in different settings. The category therefore describes circulation and prestige rather than biological descent or a single religious community.

35.2 Source control: what a cultural history can and cannot prove

The evidence is strongest where institutions left durable traces: inscriptions, coins, dated buildings, Persian chronicles, Sufi letters, Sanskrit and Avahatṭa works, manuals of writing, and later manuscript traditions. Each source illuminates a different social scale. A Persian inscription on a mosque securely dates a patron and a building, but it does not measure the language of surrounding villages. A court text may reveal etiquette and political ideals without representing household practice. A Sufi letter can show an intellectual network but not the demographic size of its audience. This chapter therefore distinguishes documented participation in Persianate forms from claims of wholesale cultural replacement.

35.3 Bihar inside the Persian cosmopolis

From the thirteenth century, Bihar became part of the wide zone in which Persian served as a major language of administration, historical writing and learned exchange under Sultanate regimes. This location mattered because the region lay between Delhi and the middle Ganga plain to the west, Bengal to the east, and the Himalayan routes of Mithila and Nepal to the north. Political control shifted among Delhi, Bengal, Jaunpur and local rulers, yet the prestige of Persian documentary and courtly forms could outlast particular dynasties. Bihar’s Persianate history was therefore not a straight line from one capital. It was produced by overlapping centres, mobile personnel and repeated acts of adaptation.

Figure 136 — Persianate culture as a network rather than an ethnicity

35.4 Persian as an administrative technology

Persian's importance in medieval Bihar lay partly in its capacity to standardise political communication across linguistic regions. Orders, revenue correspondence, petitions, appointment letters, diplomatic messages and other records depended on recognised formulae and trained scribes. This did not imply that all local administration was conducted in Persian at every level. Oral mediation, local scripts and vernacular record keeping remained necessary, especially where rulers governed through existing landed and village institutions. Persian functioned most clearly in the higher documentary zones of states and courts, where it connected provincial officials to wider Sultanate conventions.

35.5 Tirhut/Mithila at the edge of several Persianate courts

Tirhut was rarely an imperial centre, but that peripheral position did not make it culturally isolated. Oiniwar rulers and neighbouring chieftains operated within the reach of Delhi, Bengal and especially the Sharqi kingdom of Jaunpur. Tribute, military pressure, recognition, diplomacy and political refuge created channels through which scribes, envoys, texts and political vocabulary travelled. The later Vidyapati Ṭhakkura's world illustrates this condition particularly well: a small Mithila court could remain grounded in Sanskrit learning while being acutely aware of the political styles and urban worlds of Persianate North India. Peripheral courts could therefore be active nodes rather than passive recipients.

35.6 Anga and the eastern Persianate corridor

The Anga zone was differently positioned. Bhagalpur–Champa, Kahalgaon and the routes toward Monghyr/Munger lay close to Bengal's political and commercial sphere. Pre-Mughal inscriptions from Champanagar and Bhagalpur record mosque foundations under Bengal sultans, demonstrating the presence of officials, patrons and monumental forms tied to that eastern courtly world. Such inscriptions do not justify describing all of Anga as culturally Persianised, but they provide unusually firm local anchors. They show that the Persianate frontier was not merely an abstract influence from distant capitals: it was materialised in named officers, dated structures, scripts and institutional foundations.

35.7 Courts, offices and the social economy of scribal labour

Persianate culture depended on people who could write, calculate, translate, remember formulae and move between patrons. Courts required secretaries, accountants, revenue specialists, copyists, messengers and interpreters; military establishments generated further paperwork; religious institutions produced endowment and correspondence traditions. Literacy therefore had an occupational economy. Training in prestigious documentary forms could create mobility across courts without dissolving older learned identities. The later expansion of Persian-literate service groups in North India had medieval foundations in these dispersed networks of skilled labour. Mithila's own traditions of scholastic and documentary expertise participated in this wider transformation on selective terms.

35.8 Inshā', letter writing and the craft of political language

The Persianate world treated formal correspondence as a learned art. Inshā' encompassed models of letters, petitions and documents whose vocabulary, salutations and structure encoded hierarchy. The importance of such technique is visible beyond Persian-language texts themselves. A ruler or scholar who needed to correspond across political boundaries had to understand how authority was phrased and how rank was signalled. Documentary competence therefore became a form of political literacy. In Mithila, this is especially significant because Sanskrit intellectual production did not simply retreat before Persian; it could respond by systematising its own documentary knowledge in ways shaped by a multilingual political environment.

Political allegiance changed; cultural and documentary circulation crossed dynastic borders.

Figure 137 — Mithila–Anga inside regional Persianate circulation

35.9 Likhanāvalī and the later Vidyāpati Ṭhakkura's documentary world

This project distinguishes the later Vidyāpati Ṭhakkura from the earlier Mahākavi Vidyāpati. The later author's Likhanāvalī, a Sanskrit manual concerned with letters and documents, is central to understanding fifteenth-century Mithila's encounter with Persianate documentary culture. Modern scholarship has shown that his political and epistolary works were created in an environment where Persian models of statecraft and writing were familiar. The text should not be reduced to a Sanskrit translation of Persian practice; its categories draw on Sanskrit learned traditions. Its historical value lies in the entanglement: a Mithila

intellectual recast inherited knowledge for a world in which multiple documentary cosmopolitanisms coexisted.

35.10 Kīrtilatā and the urban imagination of the “city of the Turks”

Kīrtilatā offers a different kind of evidence. Its political narrative places Mithila princes in contact with the Sharqi sphere and evokes urban life beyond the local court. The work is literary and rhetorical, so individual scenes cannot be treated as neutral ethnography. Yet its very intelligibility presupposes familiarity with a social world in which Persianate cities, military power, merchants and courtly audiences were part of Mithila’s political horizon. The text helps recover perception: Persianate urbanity was neither wholly alien nor identical with Mithila. It was a neighbouring field of power with which local elites negotiated, observed and sometimes emulated.

35.11 Justice, kingship and portable political ethics

One of the most influential Persianate political ideals was the linking of sovereignty to justice. In Persian political literature, a ruler’s legitimacy depended on maintaining order, protecting cultivation and ensuring a flow of revenue that in turn sustained the state. Comparable emphases appear in several Indian traditions, and historians must avoid claiming exclusive origin for every shared idea. The important point is that by the fourteenth and fifteenth centuries concepts of just rule circulated across linguistic boundaries with new intensity. Mithila’s political thinkers encountered an environment in which Sanskrit nīti, dharmasāstra and Persianate advice literature could address overlapping problems of authority, conduct, taxation and social order.

35.12 Titles, protocol and the performance of rank

Persianate court culture made hierarchy visible through titles, seating, robes, audience procedure, honorifics, seals and styles of address. Such forms mattered because political relationships were often negotiated between unequal but semi-autonomous rulers. A local chief might preserve internal authority while acknowledging a larger sultan through tribute or titulature. The adoption of a title or diplomatic formula therefore cannot be read mechanically as total cultural submission. It could be a strategic language of recognition. In border regions like Mithila, where autonomy was repeatedly bargained rather than absolutely possessed, protocol became a practical instrument for surviving among stronger neighbours.

35.13 Persian vocabulary and vernacular contact

Language contact leaves traces unevenly. Persian administrative, military, commercial and courtly terms entered many North Indian vernaculars, but borrowing rarely replaced their grammatical structure. Mithila and Anga participated in this larger pattern through multilingual contact, especially in towns, courts, markets and official transactions. The chronology of individual loanwords requires philological care; later Maithili or regional usage cannot automatically be projected into the fifteenth century. Still, the historical setting explains why vocabulary associated with office, documents, clothing, food, urban life and material culture could circulate without requiring speakers to abandon their local languages.

35.14 Multilingual intermediaries and translation as everyday governance

States operating across linguistic regions depended on intermediaries. A Persian order might be explained orally in a vernacular, converted into a local account, or implemented through officials whose practical competence was multilingual rather than literary. Sanskrit scholars, Maithili-speaking landed groups, Persian-

trained clerks, merchants and religious specialists could therefore meet inside the same administrative process without sharing one cultural identity. Translation was not only a literary act; it was an everyday technology of rule. This layered communication helps explain how Persianate forms could penetrate selected institutions while village speech, customary practice and regional textual traditions remained resilient.

Documentary contact can be deep even when everyday speech remains multilingual.

Figure 138 — The documentary interface between Persianate and Sanskrit-Maithili worlds

35.15 Sharafuddin Maneri and Persian Sufi prose in Bihar

The fourteenth-century Sufi Sharafuddin Ahmad Maneri provides some of the strongest evidence for Persian as a language of religious thought in Bihar. His letters, preserved in major collections and studied in modern translations, connect Bihar to a transregional Sufi intellectual world. The prose is important not because it proves Persian was widely spoken, but because it shows that Bihar contained audiences capable of participating in sophisticated Persian religious correspondence. Sufi Persian operated alongside Arabic scriptural learning and local languages of teaching and devotion. This layered linguistic practice is characteristic of the Persianate sphere: cosmopolitan textual prestige could coexist with vernacular religious communication.

35.16 Khanqahs, discipleship and the circulation of people

A Sufi lodge was not simply a building. It gathered teachers, disciples, visitors, petitioners, donors and travellers, and it could connect local concerns with distant intellectual lineages. Bihar's Sufi centres therefore helped move ideas, reputations and texts along routes that also carried merchants and officials. Their influence on Mithila and Anga should be reconstructed from documented links rather than assumed from proximity, but proximity mattered: pilgrimage and discipleship did not stop at political borders. Khanqahs formed one institutional layer through which Persian literary and ethical vocabulary could circulate beyond formal government.

35.17 Arabic-Persian inscriptions as dated cultural anchors

The corpus of Arabic and Persian inscriptions from Bihar is indispensable because it converts broad cultural claims into dated local evidence. Foundation records identify patrons, officials, rulers, religious buildings and calligraphic conventions. In many cases Arabic carries Qur'anic or devotional formulae while

Persian appears in historical or poetic portions, revealing functional bilingualism within the same inscriptional culture. The distribution is uneven, reflecting both historical concentration and survival. Even so, these stones anchor Persianate culture materially: they record people who commissioned, carved, read and recognised a shared epigraphic language of authority.

35.18 Champanagar–Bhagalpur: Bengal Sultanate inscriptions in Anga

Anga offers a particularly concrete case. A Champanagar inscription records a mosque foundation in 1367 during the reign of Sikandar Shah of Bengal, and another record from the same broad urban zone dates a mosque to 1491 under Muzaffar Shah. Other fifteenth- and early sixteenth-century records from Bhagalpur likewise connect local building activity with Bengal Sultanate officers and titlature. These records demonstrate recurring eastern political links across more than a single campaign. They also show that calligraphy, patronage and religious architecture were embedded in an administrative landscape that reached into the old Anga region.

35.19 Architecture, calligraphy and the social life of surfaces

Persianate material culture was communicated through buildings as well as books. Mosques, tombs, gateways and other structures organised space and displayed inscriptions, geometric pattern, vegetal ornament and calligraphic prestige. Local builders necessarily worked with available stone, brick, timber and artisanal traditions, so regional monuments should not be imagined as imported replicas. Architecture is best understood as collaborative production. The Persianate element lay in institutional forms, inscriptions, patronage and aesthetic vocabularies that local craftsmen translated into regional materials and techniques. Such buildings made transregional culture visible to people who might never read a Persian manuscript.

35.20 Coins, names and sovereignty in circulation

Coins carried political language farther than many manuscripts because they travelled through taxation, markets and payment. Sultanate coinage used Arabic and Persian titlature to declare sovereignty and religious legitimacy, while weight standards and mint practice tied local economies to larger political systems. Coin circulation in Bihar and eastern India therefore belongs to the material history of Persianate rule. A coin found in a region does not prove direct administrative control at the moment of deposition, but clusters and mint histories can illuminate commercial and political connections. Numismatic evidence is strongest when read alongside inscriptions and textual chronology.

35.21 Dress, food and objects: slow cultural histories

Courtly prestige can influence dress, cuisine, weaponry, horse equipment, furniture and decorative objects, but these are among the hardest changes to date precisely in Mithila. Texts often describe elite consumption selectively; surviving objects may lack secure provenance; later practices are easily projected backward. The safest approach is to identify channels rather than invent inventories. Courts, garrisons, merchant routes and Sufi institutions created repeated opportunities for borrowing. Material forms could become locally naturalised without users understanding them as foreign. Persianate culture at this level was often a slow history of selection and recombination rather than a sudden package of imported customs.

35.22 Roads, rivers and manuscript circulation

Books and letters moved along the same broad infrastructure as people and goods. The Ganga corridor linked Bihar westward and eastward; tributaries, ferries and overland routes connected the river to Mithila,

Anga and Nepal. Manuscripts could travel with scholars, officials, merchants or disciples, while court correspondence moved through organised messenger systems. The circulation of texts therefore depended on ordinary transport and political security. A cultural map centred only on capitals misses the routes that made cosmopolitanism possible. Mithila and Anga were connected because rivers and roads repeatedly brought their local institutions into contact with larger documentary and commercial worlds.

35.23 Education and the reproduction of Persianate competence

Persianate institutions reproduced themselves through training. Secretaries learned composition and formulae; religious scholars studied Arabic and Persian texts; aspiring courtiers acquired etiquette, poetry and moral literature. The density of such education in medieval Mithila is difficult to quantify, and later Mughal-era evidence should not be projected backward wholesale. Yet the existence of Persian writing, inscriptions and Sufi correspondence in Bihar, together with documentary engagement in fifteenth-century Mithila, presupposes teaching networks. Literacy was therefore not merely an individual accomplishment; it depended on teachers, exemplars, copying practices, paper, patronage and communities that valued the skill.

35.24 Non-Muslim participation in Persianate institutions

Persianate culture was never confined to Muslims. Across North India, Hindu scribal and learned groups increasingly acquired Persian because it opened access to service, patronage and intellectual exchange. For the fifteenth-century Mithila case, the later Vidyāpati Ṭhakkura is more revealing than later Mughal examples because his Sanskrit works show engagement with a neighbouring Persianate political culture from within an Indic learned tradition. Participation did not require conversion or abandonment of Sanskrit. It could produce bilingual or conceptual competence in which different canons were selectively compared, translated and redeployed.

35.25 Women and the archival imbalance

The documentary archive of Persianate culture disproportionately names male rulers, saints, officials, scholars and patrons. That imbalance cannot be converted into an assumption that women were absent from the social processes described here. Court households, migrant families, artisanal production, property transmission, hospitality and religious patronage all involved women, but the surviving record often makes them visible only indirectly. Later evidence from elite households cannot automatically fill medieval gaps. A responsible social history therefore records the silence itself: Persianate institutions were reproduced through households as well as offices, yet the documentary forms that survive privilege male public actors.

35.26 Rural reach: influence was uneven

The existence of Persianate courts and inscriptions does not imply uniform penetration into rural society. Most cultivators encountered states through revenue demands, local intermediaries, markets, policing and occasional military movement rather than through Persian literary education. Village religious and linguistic life could remain overwhelmingly local even when superior officials used Persian documentation. This unevenness is historically important. Cosmopolitan culture often concentrated in courts, towns, route centres, learned institutions and service networks, while its effects in villages arrived indirectly through fiscal vocabulary, objects, patronage patterns and the movement of people.

35.27 Anga between Bengal and Bihar: political geography matters

The eastern districts repeatedly moved within the orbit of Bengal sultans as well as Bihar-based powers. Inscriptions from Champanagar and Bhagalpur, and records associated with Monghyr/Munger, indicate that the old Anga region could be integrated into political networks different from those shaping northern Mithila at the same moment. Treating Mithila and Anga as one undifferentiated medieval unit would therefore obscure the evidence. Their histories were connected but not identical: Mithila's fifteenth-century courts negotiated heavily with Jaunpur and neighbouring powers, while Anga's eastern towns often reveal stronger Bengal-facing institutional signatures.

35.28 Nepal and the Tarai as a northern interface

Mithila's Persianate connections also need a northern dimension. Political refugees, scholars, merchants and court personnel moved between the plains and Nepal, as earlier chapters have shown. Persian was not the dominant cultural language of medieval Nepal, yet the Tarai linked Nepalese polities to a North Indian world increasingly shaped by Persianate diplomacy and commerce. Transmission across this frontier was therefore selective. Sanskrit, Newar, Maithili and other traditions remained powerful, while political information, goods and people carried knowledge of Sultanate institutions northward. The borderland should be seen as an interface, not a line separating sealed cultural zones.

Figure 139 — Evidence firewall for reconstructing Persianate culture

35.29 Evidence firewall: entanglement without civilisational binaries

The strongest interpretation is neither a story of untouched “Hindu Mithila” nor one of complete “Islamic Persianisation.” Both frames turn complex social history into retrospective civilisational blocs. The evidence instead shows entanglement: Persianate administrative and literary practices gained prestige; Sufi Persian flourished in Bihar; Bengal Sultanate inscriptions appeared in Anga; Mithila intellectuals responded to neighbouring political cultures; and local languages, Sanskrit learning, ritual systems and village institutions remained active. Different forms of culture could coexist within the same person or institution. Historical explanation must therefore identify specific channels of borrowing and specific limits to them.

35.30 Conclusion: a connected cultural field before Mughal standardisation

By the early sixteenth century, Mithila and Anga already participated in a Persianate cultural field, but not in identical ways and not at equal social depth. Persian functioned as a language of administration, high correspondence, historical writing and Sufi thought in Bihar. Courtly concepts and documentary techniques travelled through Delhi, Jaunpur and Bengal; inscriptions gave those connections material form in Anga; and fifteenth-century Mithila scholarship demonstrates selective intellectual engagement. None of this requires imagining a single process of cultural replacement.

The importance of the period lies precisely in its plurality. Persianate forms became part of the region's repertoire before the much stronger Mughal standardisation of Persian administration considered later in this volume. Sanskrit, Maithili, Avahatṭa, Arabic and vernacular practices continued to occupy their own domains while overlapping through scribal labour, diplomacy, markets and religious networks. Chapter 36 therefore turns from this connected cosmopolitan field to the wider question of languages before modern standardisation.

Table 35.1 — Persianate culture and Mithila–Anga: evidence, use and limit

Evidence	What it can establish securely	Best historical use	Limit / caution
Arabic–Persian inscriptions	Dated patrons, rulers, officials, buildings, scripts and titulature	Anchor Persianate institutions in specific places such as Bihar Sharif, Champanagar and Bhagalpur	Survival is selective; one monument cannot measure language or population
Persian chronicles and court texts	Political claims, campaigns, offices, diplomatic vocabulary and ideals of sovereignty	Reconstruct the political field linking Delhi, Jaunpur, Bengal and Bihar	Court-centred and rhetorical; weak for everyday rural life
Sufi letters and malfūz traditions	Persian religious prose, named disciples, correspondence and intellectual networks	Trace learned and devotional circulation, especially around Sharafuddin Maneri	Audience size and vernacular reception are difficult to quantify
Vidyāpati Ṭhakkura's works	Fifteenth-century Mithila awareness of neighbouring courtly and documentary worlds	Study selective intellectual entanglement across Sanskrit, Avahatṭa and Persianate political culture	Literary and normative texts are not transparent social description
Coins and material culture	Sovereignty, titulature, mints, circulation and selected aesthetic conventions	Connect political economy to the material spread of Sultanate forms	Find spots may reflect trade or later deposition rather than direct control
Architecture and calligraphy	Institutional patronage, local craft translation and visible cultural forms	Study how transregional forms were materialised in regional settings	Buildings are often restored, relocated or unevenly preserved
Later histories and memory	Persistence of Persianate vocabulary, genealogies and retrospective regional interpretation	Track long afterlives and identify leads to earlier sources	Must not be projected backward without independent medieval evidence

PART V

**LANGUAGE, LITERATURE AND
KNOWLEDGE AS SOCIAL HISTORY**

Chapters 36–43

Chapter 36 — Languages Before Modern Standardisation

Before grammars, censuses, school systems, print institutions and modern language movements imposed sharper names and norms, the Mithila–Vajji–Anga region was multilingual in a more fluid sense. People spoke local vernaculars, learned Sanskrit for specific intellectual and ritual purposes, encountered Prakrit, Apabhramśa and Avahaṭṭa as literary categories and inherited registers, and later moved through political worlds in which Persian and Arabic also mattered. The task is therefore not to search for a single moment when one modern language suddenly “began,” but to reconstruct how speech, writing, genre, script, mobility and institutional prestige interacted across centuries.

36.1 The problem: language history before fixed language borders

Modern maps encourage the eye to imagine languages as territories separated by lines. That model is useful for administration and contemporary language policy, but it is hazardous when projected into the medieval past. Speech normally changed by degree across neighbouring villages and market zones. A traveller moving from western Vajji country through central Mithila toward Anga could encounter shifts in pronunciation, vocabulary and morphology without crossing a point where one complete linguistic system ended and another began. Written culture added a second layer: the language of a manuscript could differ sharply from the speech of its patron, scribe or audience. A source-critical history therefore treats “Maithili,” “Bajjika,” “Angika,” “Sanskrit,” “Avahaṭṭa” and “Persian” as historically situated labels and registers rather than timeless boxes. The question is not which modern community possessed a medieval district, but which linguistic resources were available to particular speakers, writers and institutions at particular times.

36.2 Sources: surviving writing is not a transcript of ordinary speech

The archive is structurally unequal. Inscriptions survive because stone and copper endure; scholastic manuscripts survive because institutions copied them; courtly poems survive because patrons valued them. Everyday conversation, women’s domestic speech, children’s language, bargaining in weekly markets and the speech of mobile labourers were rarely written down. Historical linguistics can infer older phonology and morphology by comparing later forms, but inference is not direct recording. Literary texts also stylise language according to metre, genre and learned convention. For this reason the chapter uses several evidence streams together: dated or datable inscriptions, manuscripts, literary works, grammars compiled much later, comparative Indo-Aryan linguistics, script history, and regional historical context. Where these streams agree, reconstruction is stronger. Where only a later label is available, the chapter states the limitation instead of turning a retrospective classification into a medieval fact.

36.3 Sanskrit as a persistent high register, not the speech of an entire population

Sanskrit remained central to learned life across Mithila for many centuries. Philosophical debate, ritual manuals, legal reasoning, scholastic commentary, royal praise and portions of documentary practice all used Sanskrit because it connected local intellectuals to transregional traditions. This durability can easily be misunderstood. Sanskrit prestige does not prove that cultivators, artisans or market populations used Sanskrit as their everyday language. Nor does the appearance of Sanskrit in a charter erase local speech. The more plausible social model is functional multilingualism: specialists mastered Sanskrit to differing degrees while vernaculars continued in households, fields, markets and oral performance. Mithila’s reputation for scholastic learning made this layered arrangement especially visible, but it was part of a wider South Asian

pattern in which a cosmopolitan written language coexisted with regional speech. The distinction between register and mother tongue is essential to every later section of this chapter.

Figure 140 — Language ecology before modern standardisation

36.4 From Old to Middle Indo-Aryan: descent is not a straight written chain

Maithili belongs to the Indo-Aryan family, and comparative work traces major features of eastern New Indo-Aryan through developments from Old and Middle Indo-Aryan. Yet the historical path should not be pictured as one book-language mechanically turning into another. “Prakrit” itself names several literary and grammatical traditions as well as Middle Indo-Aryan speech phenomena. Spoken varieties changed continuously while written conventions could remain conservative. Sound change, reduction of inflection, growth of analytic constructions and new verbal patterns accumulated over long periods and at different rates. Subhadra Jha’s *Formation of the Maithili Language* remains a foundational diachronic synthesis, while later linguistics cautions against treating every modern form as derivable through a single Sanskritic line. Contact with neighbouring Indo-Aryan varieties and non-Indo-Aryan substrates also formed part of the regional history. Genealogy is therefore necessary, but genealogy alone is not a social history of language.

36.5 Prakrit as literary memory and analytical category

Prakrit traditions mattered to eastern India through literature, drama, grammar and inherited ideas about the relation between refined and regional speech. A Sanskrit drama could allocate different Prakrits to characters according to genre conventions, but that allocation is not a sociolinguistic census. Grammarians classified speech according to learned systems that may preserve real regional features while also regularising them. The category “Māgadhi,” for example, has an important place in descriptions of eastern Middle Indo-Aryan, yet it cannot simply be equated with every vernacular historically spoken across the later territories of Bihar and Bengal. For Mithila–Vajji–Anga, Prakrit evidence is most useful when it helps explain a broad eastern Indo-Aryan development or a textual convention. It is least reliable when a literary language-name is transformed into a precise political map. This distinction prevents philological classification from becoming retrospective territorial history.

36.6 Apabhraṃśa and Avahaṭṭa: transitional written worlds

Apabhraṃśa and Avahaṭṭa occupy a difficult but productive position between learned Middle Indo-Aryan traditions and the increasingly visible regional vernacular literatures of the later medieval period. The terms can refer to literary registers rather than to one uniform spoken language. Their forms vary by author, region and manuscript transmission. In eastern India, Avahaṭṭa became particularly important for poetry that stood close to emergent vernaculars while retaining supra-local literary conventions. The safest interpretation is therefore layered: Avahaṭṭa can preserve evidence for linguistic change and regional vocabulary, but an Avahaṭṭa poem is not a phonographic recording of a village conversation. In the Mithila tradition, its importance becomes especially clear in the later Vidyāpati Ṭhakkura's courtly works, which belong to a different historical context from the earlier Maithili Padāvalī tradition recognised by this volume.

36.7 The local vernacular existed before it became easy to see in manuscripts

A written vernacular does not appear at the same moment as the speech from which it draws. By definition, the households and settlements of north Bihar and adjoining Nepal had local Indo-Aryan speech communities before those varieties became abundant in surviving manuscripts. The earliest written evidence is therefore a terminus for visibility, not a birth certificate. Comparative morphology and phonology also imply long development before the first substantial prose or poetry that modern scholars call Maithili. This principle is especially important because manuscript survival is accidental. A single lost collection can shift the apparent beginning of a literary tradition by centuries. Historians should therefore distinguish three dates: the period in which linguistic features were probably present in speech, the date of the earliest surviving text displaying them, and the later date when a modern scholarly name was applied consistently. Collapsing these dates creates false precision.

36.8 Early Maithili as a cluster of features rather than a modern standard

When early vernacular material is identified as Maithili, the term should mean that a significant cluster of phonological, morphological, syntactic and lexical features aligns with the historical development of Maithili. It should not imply conformity to a twentieth- or twenty-first-century spelling standard. Medieval scribes varied; manuscripts were recopied; orthography could reflect Sanskrit habits or local graphic practice; and authors could mix registers within one work. Early Maithili therefore needs to be recognised through converging linguistic evidence rather than by the presence of one modern shibboleth. This approach also allows internal variation to remain visible. The future standard language was selected from a larger field of regional speech. Some forms later became marked as dialectal, rustic, eastern or western only after standardisation created a stronger centre against which variation could be measured.

36.9 Varṇa-ratnākara: a major early vernacular prose witness

Jyotiśvara's Varṇa-ratnākara, conventionally placed in the early fourteenth century, is one of the strongest surviving witnesses for an early Maithili prose tradition. Its importance lies not in supplying a complete grammar of contemporary speech but in showing that an extensive vernacular descriptive prose could sustain lists, social scenes, places, occupations, sensory detail and rhetorical catalogues. The surviving manuscript history also reminds us that texts travelled: the work came to modern scholarly attention through manuscript searching connected with Nepal and Bengal, demonstrating the wider circulation of Mithila's textual culture. Because the text is highly crafted, its vocabulary is richer and more stylised than ordinary conversation would have been. Even so, it materially shifts the evidentiary balance. Vernacular prose was not merely an oral substrate beneath Sanskrit; it could itself become a sophisticated written medium.

36.10 What Varṇa-ratnākara can tell us—and what it cannot

The work is a linguistic source precisely because it is a literary source, but the two uses must not be confused. Its lexical density can illuminate semantic fields, urban and courtly vocabulary, occupational terminology and descriptive conventions. Its grammatical forms can be compared with later Maithili. Yet a lexical item in the text does not prove equal use across all villages or social groups. Nor can manuscript spelling be assumed to reproduce pronunciation mechanically. The text's social descriptions are rhetorical compositions, not questionnaires. The strongest historical use is therefore triangulation: linguistic forms are compared with other early eastern Indo-Aryan evidence, later Maithili, and the institutional context of the Karnata-era court. The result is a robust witness to vernacularisation without an exaggerated claim that one manuscript fixes every boundary or social register of fourteenth-century Mithila.

Figure 141 — Evidence bands for vernacular formation, c. 600–1600 CE

36.11 The project's two-Vidyāpati chronology and linguistic periodisation

This volume maintains its adopted distinction between Mahākavi Vidyāpati, treated here as the pre-Jyotirīśvara Maithili Padāvalī poet, and the later Vidyāpati Ṭhakkura associated with the Oiniwar court and Sanskrit/Avahaṭṭa works such as Kīrtilatā, Kīrtipatākā, Puruṣaparīkṣā, Gorakṣavijaya and Likhanāvalī. The distinction matters linguistically because otherwise texts belonging to different registers and historical contexts are collapsed into one authorial biography. Under the adopted framework, the earlier Padāvalī witnesses a Maithili poetic register before Jyotirīśvara, whereas the later Ṭhakkura demonstrates the continued coexistence of Sanskrit, Avahaṭṭa and vernacular resources in the fifteenth-century courtly world. Chapter 38 treats the two contexts directly. Here the methodological point is narrower: a history of language must date texts and registers before using them to construct a linear literary genealogy.

36.12 Multilingual courts: choice of language followed function

A medieval court was not linguistically uniform. Praise, ritual, legal reasoning, correspondence, account keeping, entertainment and oral negotiation could call for different linguistic resources. Sanskrit carried immense learned authority; vernaculars reached audiences and performed regional identity; Avahaṭṭa offered a flexible literary medium; and, after the expansion of Sultanate political networks, Persian increasingly mattered in diplomacy and administration beyond or alongside local practices. The presence of several

languages in one court is therefore not evidence of confusion. It is evidence of specialisation. A ruler's household might patronise a Sanskrit scholar and a vernacular performer while envoys dealt with Persianate courts through scribes and interpreters. This functional distribution explains why literary history built around only one language misses much of the actual social infrastructure of writing.

36.13 Script is not language

One of the most persistent historical errors is to identify a language with one script. Maithili has a strong historical association with Tirhuta/Mithilākṣara, but language and graphic system are analytically different. A Maithili text may be copied in more than one script; Sanskrit may also appear in Tirhuta; and the use of Nāgarī or another script does not automatically change the language of the words. Script choice can reflect scribal training, manuscript genre, patronage, availability of type, administrative practice or later editorial intervention. Chapter 39 examines Tirhuta and scribal culture in detail. For the present chapter, the rule is simple: orthography is evidence about writing, not a direct territorial label for speech. This distinction becomes even more important in the early modern and colonial periods, when script politics contributed to modern language identities.

36.14 Manuscript copying creates linguistic layers

A medieval text may survive only in a manuscript copied centuries later. Copyists can modernise spelling, substitute familiar words, regularise morphology, misunderstand older forms or silently mix their own conventions with those of the exemplar. Conversely, learned scribes can preserve archaic spellings after pronunciation has changed. Philology therefore distinguishes the date of composition from the date and place of a surviving copy. For early Maithili, this principle is indispensable. A fifteenth- or seventeenth-century manuscript of an older composition is evidence both for the earlier work and for the later transmission history, but not in identical ways. Variant readings across copies can sometimes reveal the movement of a text between regions. They can also warn against treating an editor's normalised printed text as if it were the exact medieval manuscript surface.

36.15 Western Mithila and Vajji: gradients later named Bajjika

The western portion of the wider Mithila–Vajji zone participated in a speech continuum shaped by contact toward the Gandak, north Bihar and adjoining eastern Uttar Pradesh. Modern Bajjika naming is valuable for describing contemporary and recent historical speech communities, and Chapter 42 studies that history directly. For the medieval period, however, the evidence does not justify drawing a sharp Bajjika–Maithili frontier on a modern district map. Features could diffuse through marriage networks, fairs, river crossings and market towns. Local identity and linguistic practice need not coincide exactly. The correct historical formulation is therefore that western vernacular zones displayed patterns that later classifications describe as Bajjika and related varieties, while remaining connected to central Mithila through continuous social interaction. This preserves linguistic difference without inventing a medieval language border for which no contemporary survey exists.

36.16 Eastern Mithila and Anga: gradients later named Angika

The eastern side of the region was equally connected and equally variable. Speech in the old Anga–Bhagalpur–Munger zone interacted with central Mithila, Magadhan varieties and the languages of Bengal. Modern Angika naming identifies a real linguistic and cultural field, which Chapter 41 treats on its own terms. But medieval evidence again favours a continuum over a hard line. Rivers and trade routes brought

eastern settlements into repeated contact with Bengal, while political and religious networks connected them westward and northward. A form that appears “eastern” in later classification may therefore reflect long contact rather than a neatly bounded ancestral language. Separating contemporary recognition from medieval reconstruction protects both: Angika need not be denied in order to avoid projecting its present boundary backward.

36.17 Central Mithila: prestige does not mean uniform speech

Darbhangā and the central Mithila heartland later became particularly important in the codification and prestige economy of Maithili. That later history can create the illusion that a single central speech norm governed the whole region from the beginning. Medieval social geography was more plural. Courts, scholarly centres, agrarian settlements and pilgrimage sites formed nodes, not a uniform linguistic surface. Even within areas later treated as the Maithili core, pronunciation and lexicon could vary by locality, occupation, status, gender and mobility. A prestige literary variety can spread without erasing local speech. The emergence of a recognised written Maithili therefore needs to be separated from the much later production of a standard norm in grammar, print and education. The same language can possess a literary centre while remaining internally diverse.

36.18 Nepal Tarai and Kathmandu Valley: language moved with people and patronage

Mithila’s linguistic history cannot stop at the modern India–Nepal boundary. The Karnata political world itself straddled the plains below the Himalayan foothills, and later movements of rulers, scholars, performers and manuscripts carried Maithili northward. Medieval and early modern Nepal preserves substantial evidence for Maithili literary use, especially in court and performance settings under later dynasties. This does not mean that Maithili replaced Newar, Nepali or other local languages. It entered a multilingual courtly ecology in which languages could be selected by genre and patronage. Manuscripts preserved in Nepal are therefore doubly important: they document Maithili’s wider literary reach and they show that archives survive outside the political territory in which a work originated. The borderland was a corridor, not a linguistic wall.

REGIONAL CONTINUUM, NOT MEDIEVAL HARD BORDERS

Modern language names remain useful, but must not be converted into fixed medieval frontiers.

*Figure 142 — Regional speech continuum without hard medieval language borders***36.19 Persian and Arabic contact: lexical borrowing follows institutions unevenly**

Chapter 35 traced Persianate culture as a transregional field. Linguistically, that field created opportunities for Persian and Arabic vocabulary to enter regional speech through administration, military organisation, trade, dress, material culture and religious institutions. Borrowing, however, must be dated item by item wherever possible. A Persian-derived word common in modern Maithili cannot automatically be assigned to the fourteenth century. Some loans may be early; others spread under Mughal or colonial regimes. Borrowing also does not imply grammatical replacement. The basic structure of Maithili remained Indo-Aryan while its lexicon continued to absorb words from many sources. Towns, courts and market networks probably experienced such contact earlier and more densely than isolated rural settlements. Linguistic influence therefore had a social geography.

36.20 Administrative multilingualism and the work of intermediaries

Government depends on communication across levels. A Persian order from a superior court had to be understood by local officials; a revenue demand had to reach cultivators; petitions and disputes often moved upward from people who did not command the language of the highest office. This created work for scribes, translators, accountants and oral intermediaries. Sanskrit documentary habits, vernacular explanation and Persianate formulae could therefore coexist within one administrative chain. The resulting archive is deceptive because the language that survives on the most durable document may represent only the top layer of a multilingual transaction. Social history must reconstruct the missing translations beneath it. The same insight applies to land grants discussed in Chapter 26: a formal text addressed in a learned register still presupposed oral communication with resident cultivators.

36.21 Markets, pilgrimage and seasonal mobility as engines of convergence

Language contact did not require royal policy. Weekly markets, river ferries, pilgrimage routes, marriage journeys, cattle movement, craft circulation and seasonal labour brought speakers from adjacent zones into recurrent contact. Repeated low-level contact can diffuse pronunciations and words without producing a literary record. This is one reason dialect continua are historically plausible even when manuscripts are sparse. The Ganga corridor connected Anga with Bihar and Bengal; north–south routes linked central Mithila with the Tarai; rivers both separated and connected settlement clusters. Market speech may have encouraged accommodation, code-switching and the use of widely intelligible forms. Such practices are almost invisible in elite texts, but they are necessary to explain why linguistic features rarely stop at political frontiers.

36.22 Oral genres preserve language differently from manuscripts

Songs, ritual formulae, tales, proverbs, wedding genres and performance traditions can preserve archaic words and structures, yet oral transmission also changes continuously. A song recorded in the nineteenth or twentieth century may contain old material, but its current wording cannot simply be dated to the supposed origin of the tradition. Performance adapts to audience and memory. The historical value of oral material therefore lies in patterns: recurrent vocabulary, formulaic structures, genre-specific registers and comparison across versions. Chapter 40 examines oral culture in depth. For Chapter 36, oral tradition provides a necessary corrective to manuscript bias. It reminds us that literary history captures only part of the language environment and that communities without abundant manuscripts still possessed complex verbal arts.

36.23 Gender and the hidden sociolinguistic archive

Formal manuscripts disproportionately record male authors, scribes and patrons, but household language was reproduced through women as well as men. Marriage moved women between villages and sometimes across speech zones, creating channels for lexical and phonological exchange that political histories rarely see. Women's songs and ritual speech could maintain distinctive registers; domestic labour connected generations; elite women could also participate in patronage and manuscript culture, although the archive names them less often. Because direct medieval evidence is sparse, the chapter does not invent a separate female dialect. The secure conclusion is methodological: a language history built only from named male authors cannot represent the whole speech community. Gendered mobility and oral transmission must remain part of the explanatory model even where exact forms cannot be recovered.

36.24 Social rank, occupation and repertoire

Linguistic competence was unequally distributed. A Sanskrit scholar, merchant, soldier, village headman, artisan, mendicant and cultivator could share a local vernacular while possessing very different additional repertoires. Some learned men commanded multiple written languages; others relied on oral specialists. Occupational groups that travelled—traders, performers, religious mendicants, messengers and soldiers—were especially likely to develop accommodation strategies across dialect zones. Social rank could influence access to literacy without determining the language of everyday life. The result was not a simple hierarchy in which one caste spoke Sanskrit and another spoke Maithili. Rather, registers overlapped unevenly, and individuals could move among them according to context. This repertoire model is more historically plausible than assigning one language to one social category.

36.25 Place names and personal names: useful but dangerous evidence

Inscriptions and manuscripts preserve place names and personal names that can reveal phonological adaptation, regional vocabulary and the coexistence of naming traditions. Yet names are conservative and mobile. A Sanskritised place name in a charter may differ from local pronunciation; a Persian chronicle may transliterate the same settlement differently; a scribe may use an inherited official form long after speech has changed. Personal names travel with religion, patronage and fashion. Onomastic evidence is therefore strongest when several dated examples show a pattern. A single spelling should not be used to reconstruct an entire local phonology. Historical geography benefits from names, but language history must distinguish the language of a name's recorded form from the language spoken around the named place.

36.26 The history of the name “Maithili”

Language names are themselves historical evidence. “Maithili” derives its force from the regional name Mithila and ultimately became the standard modern designation of the language. Earlier sources, however, may use regional, literary or generic labels differently, and external observers later used forms such as Tirhutiya/Tirhutia. The absence of the modern name in an early text does not prove the absence of the language; conversely, the appearance of a regional label does not guarantee that it had the same technical linguistic meaning as today. Colonial philology, especially Grierson's grammar and Linguistic Survey, greatly sharpened the classificatory visibility of Maithili in modern scholarship. That achievement must be recognised without mistaking nineteenth-century taxonomy for medieval self-description.

36.27 Colonial grammars are indispensable evidence—and late evidence

George A. Grierson's nineteenth- and early twentieth-century work documented Maithili grammar, vocabulary, scripts and regional variation with extraordinary detail. The Linguistic Survey of India created a comparative record that remains fundamental. But these works belong to a period already shaped by colonial administration, print, schooling and new ideas of language classification. They are therefore excellent sources for reconstructing recent forms and for comparative back-projection where historical linguistics permits it, but they cannot directly describe a fourteenth-century village. Grierson's categories also participated in the modern process by which languages and dialects were named, bounded and ranked. A critical history uses his data while historicising his classificatory framework.

36.28 Standardisation changes the meaning of “variation”

Before a powerful standard exists, variation is simply part of ordinary linguistic life. Once grammars, dictionaries, examinations, newspapers and schools privilege selected forms, alternatives can be reclassified as dialectal, incorrect, rustic or regional. This social transformation belongs mainly to later chapters, but it explains why modern intuition is a poor guide to medieval language. A form now considered non-standard may preserve an old feature; a prestigious modern form may have spread relatively recently. Standardisation also fixes spelling more strongly and links language identity to institutions. Chapter 36 therefore ends before that process becomes dominant. Its purpose is to recover the open field from which later standard Maithili, modern Angika and Bajjika identities, and neighbouring language norms emerged.

36.29 Evidence firewall: speech, register, script and standard must stay separate

Four analytical categories must not be collapsed. Speech is the changing everyday linguistic system used by communities. A written register is a socially selected form shaped by genre and institution. Script is the graphic technology used to represent a language. A standard is a later normative selection backed by grammars, print, education or administration. One language can use several scripts; one script can write several languages; one speaker can command several registers; a standard can emerge long after the speech it codifies. Most historical errors in this field come from substituting one category for another—for example, treating Tirhuta script as proof of one spoken boundary, or using a Sanskrit manuscript to infer Sanskrit household speech. The evidence firewall protects against such substitutions.

EVIDENCE FIREWALL FOR PRE-STANDARDISATION LANGUAGE HISTORY

Secure reconstruction requires agreement across these evidence classes, not substitution of one for another.

Figure 143 — Evidence firewall: speech, written register, script and later standardisation

36.30 Conclusion: a multilingual region before standard language regimes

Before modern standardisation, Mithila–Vajji–Anga was neither linguistically formless nor neatly partitioned into the language territories familiar today. It possessed structured repertoires: durable Sanskrit learning, Middle Indo-Aryan inheritances, Apabhraṃśa and Avahatṭa literary practices, increasingly visible Maithili vernacular writing, western and eastern speech continua, oral genres, and growing contact with Persianate institutions. Nepal was part of this circulation, not an external afterthought. The strongest history is therefore one of vernacularisation within multilingual continuity. Languages developed through speech communities and contact long before grammars fixed their boundaries. Chapter 37 can now examine the more specific question of how a literary Maithili tradition was formed, while Chapters 41 and 42 will return separately to the eastern Angika and western Bajjika zones without projecting modern boundaries backward.

Table 36.1 — Languages before modern standardisation: evidence, secure use and limit

Evidence	What it can establish securely	Best historical use	Limit / caution
Dated inscriptions and charters	Recorded language, script, names, titles and formulae at a specific time	Anchor documentary registers and onomastic forms	Formal language may differ from local speech
Manuscripts	Vocabulary, grammar, genre and scribal practice in surviving copies	Trace written vernacularisation and textual circulation	Copy date may be later than composition; scribes can alter forms
Varṇa-ratnākara and other literary texts	Substantial early vernacular forms and lexical fields	Demonstrate capacity of vernacular prose/literature	Literary style is not a transcript of everyday speech
Comparative historical linguistics	Regular correspondences and probable earlier forms	Reconstruct long-term phonological and morphological development	Reconstruction is inferential, not a dated recording
Later grammars and surveys	Detailed modern/recent grammar, vocabulary and regional variation	Provide comparative baseline and evidence for standardisation	Colonial or modern categories cannot be back-projected

Evidence	What it can establish securely	Best historical use	Limit / caution
			unchanged
Oral genres recorded later	Formulae, lexicon, performance registers and variant traditions	Recover non-manuscript dimensions of language history	Current wording cannot automatically be dated to the tradition's origin
Script evidence	Graphic conventions, scribal training and manuscript networks	Study Tīrhuta/Nāgarī and other writing practices	Script does not equal language or spoken territory

Chapter 37 — Formation of Literary Maithili

Literary Maithili did not emerge at one instant when an anonymous spoken dialect suddenly became a written language. It formed through a long interaction among regional speech, oral performance, Sanskrit learning, Prakrit–Aṣṭaśāṣa–Avahatṭa inheritances, courts, scribal households, manuscript technologies and cross-border circulation. The surviving archive is uneven: some genres are visible because manuscripts survived, others because later editors collected them, and still others lived primarily in performance. This chapter therefore reconstructs a process of vernacularisation rather than a mythical birth date. It also follows the volume’s adopted two-Vidyāpati framework: the pre-Jyotirīśvara Mahākavi Vidyāpati of the Maithili padāvalī tradition is kept distinct from the later fifteenth-century Vidyāpati Ṭhakkura associated with the Oiniwar court and Sanskrit/Avahatṭa works.

37.1 Formation, not “birth”: what a literary language requires

A spoken language can exist for centuries without leaving an archive that modern literary historians can readily see. “Formation of literary Maithili” therefore means the growth of repeatable conventions for composition, performance, copying, attribution and reception in a regional vernacular. It requires more than isolated vernacular words in Sanskrit documents. A literary language becomes historically visible when extended texts use it deliberately, audiences recognise recurring genres, scribes can reproduce it, and later writers treat earlier compositions as models. None of these developments needs to happen simultaneously. Prose may become writable before a stable dramatic convention; song may circulate orally before manuscripts record it; courtly prestige may rise after popular performance has already flourished. The historical problem is thus to identify converging evidence. Literary Maithili emerged through accumulation: vernacular grammar supplied the medium, oral culture supplied memorable forms, learned traditions supplied techniques of classification and poetics, and social institutions supplied occasions for preservation.

37.2 Vernacularisation within, not against, the Sanskrit cosmopolis

The rise of Maithili writing did not require the disappearance of Sanskrit. Sanskrit remained a major language of philosophy, ritual, law, scholarship and elite literary production across Mithila. Vernacularisation is better understood relationally: writers increasingly used a language of place for domains in which Sanskrit had long possessed transregional authority, while continuing to learn and deploy Sanskrit where appropriate. Sheldon Pollock’s wider model of a South Asian “vernacular millennium” is useful precisely because it emphasises coexistence rather than instantaneous replacement. In Mithila, Sanskrit expertise could strengthen vernacular writing by providing rhetorical categories, learned vocabulary, metrics and models of textual organisation. A writer could be highly Sanskritic in education yet choose Maithili for descriptive prose, song or stage dialogue. Literary Maithili was therefore not an anti-Sanskrit movement. It was a new allocation of linguistic functions within a multilingual cultural system.

37.3 Prakrit, Aṣṭaśāṣa and Avahatṭa as inherited literary resources

Between classical Sanskrit and the increasingly visible regional vernaculars lay a long history of Middle Indo-Aryan literary practice. Prakrit, Aṣṭaśāṣa and Avahatṭa were not merely defective stages on a ladder leading inevitably to modern languages. They were cultivated registers with their own conventions. Their metres, vocabulary, narrative habits and grammatical possibilities provided writers with models for composing outside Sanskrit. For the history of Maithili, this matters in two ways. Linguistically, some forms illuminate continuities between Middle and New Indo-Aryan. Literarily, they show that prestigious non-

Sanskrit writing was already normal before Maithili acquired a more distinct written profile. Avahaṭṭa remained available even after vernacular Maithili was capable of sustained composition; the later Vidyāpati Ṭhakkura's courtly works are an important reminder of this coexistence. Formation therefore involved selection among neighbouring registers, not a clean succession in which one language died when another appeared.

FORMATION OF LITERARY MAITHILI: AN ECOLOGY, NOT A SINGLE BIRTH DATE

Literary formation occurs when speech becomes reproducible across genres, institutions, performances and manuscripts.

Figure 144 — Formation of literary Maithili as an interacting cultural ecology

37.4 Oral literature before manuscript visibility

The manuscript archive systematically underrepresents oral performance. Work songs, wedding songs, ritual songs, narrative recitation, praise, satire, riddling and seasonal performance could develop sophisticated conventions without being copied into durable codices. When literary Maithili becomes visible in substantial written texts, it enters a world where vernacular verbal art already existed. Formulaic repetition, refrain, parallelism, dialogue and strongly patterned imagery are especially compatible with oral transmission. Later recordings cannot simply be dated back to the Middle Ages, yet the existence of mature performance systems helps explain how lyric and dramatic genres could expand quickly once written witnesses survive. Literary history must therefore resist a documentary illusion: the earliest surviving manuscript is not necessarily the earliest composition, and the earliest composition is not necessarily the earliest vernacular art. Manuscripts are evidence of preservation; performance may have supplied the deeper reservoir.

37.5 Performance as an engine of literary stabilisation

Performance does more than transmit a text; it can stabilise it. A song repeatedly sung at a court, shrine, marriage or seasonal gathering develops expected rhythms, refrains and thematic sequences. A drama creates recurring relations among dialogue, song, gesture and role. These expectations become a form of literary grammar. Performers may also preserve compositions across generations when manuscripts are lost, while manuscripts can later freeze one version of a previously variable performance tradition. For Maithili, this reciprocal relation between voice and writing is central. The growth of padāvalī, devotional song and dramatic traditions cannot be reconstructed solely from silent page-text. Melody, audience and occasion affected what was memorable and therefore what entered the canon. Literary Maithili became durable partly

because it could move between manuscript and mouth: written enough to be copied, flexible enough to be performed.

37.6 Script did not create the language, but scribal technology mattered

Tirhuta/Mithilākṣara later became a powerful marker of Maithili manuscript culture, while Nāgarī and other scripts also participated in transmission. Script, however, must not be confused with language. Maithili could be written in more than one script, and the same script could carry Sanskrit or other languages. The important historical point is institutional: a vernacular becomes easier to preserve when scribes have stable graphic conventions for representing its sounds, inflections and common words. Copying also creates networks of correction, commentary, ownership and inheritance. Manuscripts turn transient performance into transportable objects. Yet every copy introduces another historical layer: spelling may be normalised, forms altered, and marginal notes incorporated. Literary formation therefore includes the growth of a scribal ecology, but textual criticism must still distinguish composition from surviving copy.

37.7 Courts were accelerators, not solitary creators

Royal and aristocratic courts supplied patronage, audiences, scribes and occasions for literary display. The Karnata and Oiniwar worlds are therefore important to Maithili literary history. But court-centred narratives become misleading when they imply that literature was created from above. Courts recruited talent from learned households, temples, villages and itinerant networks; they also adopted genres already meaningful beyond the palace. The vernacular could serve courtly description, entertainment, devotion and public representation precisely because audiences already understood it. Patronage increased the resources available for composition and copying, while political disruption could redirect scholars and performers into new regions, including Nepal. A balanced account treats the court as a node where many social currents met. Literary Maithili was not the private invention of one dynasty: it became more visible when regional institutions chose to preserve and reward forms rooted in a broader speech community.

37.8 Learned households and the reproduction of competence

Mithila's dense traditions of Sanskrit learning helped create households in which textual competence could be transmitted across generations. Such households did not necessarily specialise in vernacular writing, but they supplied skills essential to it: grammar, metrics, poetics, manuscript preparation, legal and ritual vocabulary, and familiarity with multiple literary registers. Vernacular authorship could therefore emerge from scholars who possessed transregional learning yet chose a regional medium for particular purposes. This helps explain the technical confidence of early substantial Maithili texts. Their vernacularity need not imply distance from scholastic culture. At the same time, literary Maithili could move beyond learned households through performance and popular reception. The social formation of literature thus linked unequal institutions: elite literacy and broad vernacular intelligibility did not cancel one another; they interacted.

37.9 When vernacular grammar becomes a literary resource

A language becomes literary not by abandoning everyday grammar but by exploiting it deliberately. Honorific distinctions, pronouns, verbal endings, postpositions, particles and local idioms can create shades of intimacy, command, irony and social distance that are difficult to reproduce in a different language. Literary Maithili's strength lay partly in this proximity to regional speech. Writers could model conversation, desire, rebuke, devotion and observation with grammatical resources familiar to audiences. Yet literary language is never identical to casual speech. Composition selects, regularises and heightens forms; scribes and

performers may further reshape them. The result is a recognisable literary register built from the vernacular without becoming a phonographic transcript of one village dialect. The formation of literature therefore involves stylisation: local grammar acquires aesthetic and social functions that make it reproducible beyond the immediate speech event.

37.10 Varṇa-ratnākara as a major prose witness

Jyotirīśvara's *Varṇa-ratnākara*, conventionally placed in the early fourteenth century and preserved through later manuscript transmission, is one of the central witnesses for early literary Maithili. Its importance is not that it proves a language was suddenly born in Jyotirīśvara's lifetime. Rather, sustained vernacular prose demonstrates that Maithili could organise extensive description, classification and lexical abundance. The work ranges across social types, environments, activities and aestheticised scenes, making it invaluable not only for literary history but also for the vocabulary of material and social life. The 1940 edition by Suniti Kumar Chatterji and Babua Misra made this evidence widely accessible to modern scholarship. Because the work is highly stylised and encyclopedic, it should not be treated as a transcript of ordinary conversation. Its achievement is different: it shows a vernacular functioning confidently as an instrument of elaborate prose composition.

37.11 Description itself becomes a literary claim

The encyclopedic impulse of *Varṇa-ratnākara* is significant for vernacularisation. To name plants, objects, professions, bodies, emotions, places, performances and social situations in a regional language is to demonstrate that the vernacular can order the world. The literary force lies not merely in vocabulary lists but in the capacity to arrange perception. A cosmopolitan language does not monopolise refined description once a vernacular can sustain dense semantic fields of its own. This does not make the text "realist" in a modern novelistic sense; lists and set descriptions obey rhetorical conventions. Yet the work expands the imaginable domain of Maithili prose. It turns local lexical richness into a literary technology. That achievement becomes one foundation for later prose, drama and song, even when later authors choose very different genres.

37.12 Jyotirīśvara's dramaturgical multilinguality

Jyotirīśvara is also associated with *Dhūrtasamāgama*, a dramatic work in which Sanskrit, Prakrit and vernacular song coexist. Modern summaries of the play differ in how they label particular passages, which itself warns against forcing medieval multilingual texts into one-language categories. What matters historically is the dramaturgical principle: different registers could share a stage and perform different social or aesthetic functions. Maithili's literary growth therefore occurred inside multilingual composition, not only in monolingual books. Theatre made code choice audible. A song in a regional vernacular could create immediacy or musical pleasure while learned speech retained other roles. This mixed practice is evidence of literary confidence: the vernacular did not need to expel Sanskrit or Prakrit in order to become aesthetically consequential.

SELECTED EVIDENCE HORIZONS FOR LITERARY FORMATION

These are evidence horizons, not “birth dates” of speech, authorship or genre.

Figure 145 — Selected evidence horizons for literary formation, c. 1200–1700

37.13 Genre specialisation made the vernacular larger

No single early text can define the whole literary language. Descriptive prose, lyric song, drama, narrative, devotional composition and practical writing each recruit different vocabularies and syntactic patterns. Literary Maithili expanded as more genres became possible. Prose required connective structure and extensive naming; lyric demanded compression, voice and musicality; drama required interaction among characters and registers. Once multiple genres exist, writers can borrow techniques across them and audiences can recognise a broader literary field. This is a more useful criterion of formation than the search for a first sentence. The language becomes “larger” not because its grammar changes overnight but because the social range of things that can be done with it increases.

37.14 The pre-Jyotirīśvara Mahākavi Vidyāpati in this volume’s framework

This volume follows the project’s adopted distinction between two historical Vidyāpatīs. Mahākavi Vidyāpati is treated here as the pre-Jyotirīśvara poet of the Maithili padāvalī tradition, distinct from the later Vidyāpati Ṭhakkura of the fifteenth-century Oiniwar milieu. Chapter 38 examines the historiographical case in detail; Chapter 37 uses the distinction only to prevent two corpora from being collapsed. Within this framework, the lyric tradition demonstrates that literary Maithili cannot be narrated as beginning with Jyotirīśvara’s prose. Song and prose represent different evidence streams, and the survival history of songs is especially vulnerable to later copying, anthology-making and attributional conflation. The methodological consequence is important: chronology must be argued by corpus, manuscript and attribution, not inferred from a famous name treated as a single biographical container.

37.15 Padāvalī: literature designed for voice

The Maithili padāvalī tradition shows how a literary corpus can be structured by song rather than book architecture. Short lyric units, recurring emotional situations, refrains, musical associations and remembered authorial signatures make poems portable across performers and regions. Such portability encourages both survival and variation. A lyric may outlive the manuscript that first recorded it; conversely, a later anthology may assign a traditional song to a prestigious poet. Literary history therefore needs both aesthetic reading and textual criticism. Padāvalī also demonstrates a key stage in Maithili’s formation: the vernacular could carry

highly compressed emotional and theological meanings while remaining singable. This fusion of literary craft and performance greatly expanded the audience of Maithili beyond readers of scholastic prose.

37.16 Gendered voices, devotion and erotic language

Many eastern Indian lyric traditions speak through gendered personae—especially female voices of longing, complaint, separation or desire. These voices should not be read mechanically as autobiographical statements by the historical author. They are literary positions shaped by *rasa*, devotional interpretation, dramatic role and performance convention. In Maithili, such lyricism helped make intimate vernacular grammar aesthetically powerful. Terms of address, diminutives, bodily imagery and conversational syntax could carry theological as well as erotic meanings. Later religious reception often intensified this double valence. The result is a literature in which social voice and devotional imagination intersect. Literary formation therefore included the ability to turn locally intelligible speech forms into sophisticated personae, not simply the ability to record events.

37.17 Attribution is part of the archive, not a transparent fact

A named signature in a song, an attribution in a late manuscript and an author named by a modern editor are three different kinds of evidence. *Padāvalī* traditions are particularly susceptible to accretion because memorable poets attract later compositions. Manuscripts can also preserve variant names, omit signatures or regularise them. The safest canon therefore has layers of confidence rather than an all-or-nothing boundary. Some works may be strongly attributable; others may belong to a school, performance lineage or later imitative corpus. This principle is essential to the two-Vidyāpati problem but extends far beyond it. Literary Maithili formed through communities of use, and communities often preserve prestige by attaching texts to exemplary names. Historical criticism should respect the tradition while still testing attribution.

37.18 The later Vidyāpati Ṭhakkura: multilingual court literature, kept separate

The later Vidyāpati Ṭhakkura belongs to a fifteenth-century political and learned world and is associated in this project with Sanskrit and Avahaṭṭa works such as *Likhanāvalī*, *Kīrtilatā*, *Kīrtipatākā*, *Puruṣaparīkṣā* and related courtly compositions. Pankaj Jha’s study of fifteenth-century Vidyāpati demonstrates the value of reading this corpus in a multilingual political environment rather than reducing it to modern language nationalism. For Chapter 37, the crucial point is functional multilinguality. A single courtly milieu could value Sanskrit treatise, Avahaṭṭa narrative and regional vernacular performance simultaneously. Literary Maithili therefore did not become mature by forcing every intellectual genre into Maithili. Its formation is visible precisely in the widening ecology of choices. The two-Vidyāpati distinction prevents the Maithili lyric corpus from being used uncritically to date or interpret the later Ṭhakkura’s historical works, and vice versa.

37.19 Avahaṭṭa was a literary choice, not “failed Maithili”

Older histories sometimes describe transitional registers teleologically, as if Avahaṭṭa were only an imperfect form waiting to become a modern language. That approach obscures authorial choice. In the fifteenth century, a writer could select Avahaṭṭa because it carried particular literary prestige, narrative conventions or transregional intelligibility. Its use alongside Sanskrit and vernacular forms shows a repertoire, not confusion. For the history of Maithili, this helps define literary formation negatively as well as positively: Maithili was becoming a recognised literary option, but it was not the only non-Sanskrit option. Genre, audience and patronage still shaped linguistic selection. The existence of competing registers is evidence of a sophisticated literary market rather than an immature language.

37.20 Sanskrit remained a coexisting language of high knowledge

Even after Maithili acquired powerful literary forms, Sanskrit retained deep institutional authority in Mithila. Nyāya, ritual, jurisprudence, scholastic debate and many forms of kāvyā continued in Sanskrit. This continuity matters because modern nationalist narratives often imagine literary progress as a zero-sum shift from Sanskrit to vernacular. The historical record suggests layering instead. A scholar might write or teach in Sanskrit while hearing, speaking, composing or patronising Maithili in other settings. Sanskrit technical vocabularies also entered vernacular texts selectively. Literary Maithili grew in a bilingual or multilingual learned environment, and its distinctiveness was sharpened by that relation. The vernacular did not have to reproduce every Sanskrit function in order to possess an autonomous literature.

GENRE AND REGISTER: LITERARY MAITHILI GREW BY SPECIALISATION

No single genre “created” Maithili literature. Different genres made different parts of the vernacular writable and memorable.

Figure 146 — Genre and register in the expansion of literary Maithili

37.21 Persianate contact enlarged the multilingual field

From the thirteenth century onward, Persian and Arabic entered the political, administrative and learned environment of North India with increasing force. As Chapter 35 showed, “Persianate” should not be treated as a synonym for one religion or ethnicity. For Maithili literary history, the main consequence is a broader multilingual field. Courtly actors, scribes and travellers encountered Persian administrative vocabularies and narrative cultures while Sanskrit and regional vernaculars continued. The fifteenth-century world studied by Pankaj Jha is especially important because literary and documentary practices crossed political-cultural boundaries. Borrowed words are only one trace of contact; new genres of record, diplomacy and historical representation also matter. Literary Maithili developed in this connected environment rather than inside a sealed regional container.

37.22 Nepal as archive, audience and second centre of circulation

The political and cultural relationship between Mithila and Nepal gave Maithili an unusually important trans-Himalayan afterlife. Manuscripts in Nepal preserve texts that might otherwise have disappeared, while migration of scholars and performers carried genres into the Kathmandu Valley. Basudev Lal Das points to the significance of Maithili manuscripts in Nepalese repositories, and theatre historians note the strong role of Maithili in the Malla-period dramatic world. Nepal should therefore not be treated merely as an external “influence” on an Indian language. It became part of the archival geography of Maithili itself. This cross-

border circulation also complicates modern national narratives: works copied or performed in present-day Nepal may belong to a literary history whose social field long predated the India–Nepal border.

37.23 Malla courts and the prestige of Maithili drama

In the Kathmandu Valley, Maithili became an important literary and theatrical language under Malla patronage, particularly in the early modern period. Carol C. Davis’s history of Nepalese theatre synthesises scholarship showing that Maithili-speaking scholars and poets influenced court culture and that Maithili became a major medium of dramatic production. The precise dating and language composition of individual plays must be checked work by work, but the larger pattern is secure: a regional language from Mithila acquired high prestige beyond Mithila itself. This circulation is an important test of literary formation. A language that can be adopted by distant courts for drama has moved beyond purely local writing. At the same time, Nepalese production could reshape the language through local performance conditions and contact with Newari and other traditions. Reception was creative, not passive.

37.24 Kīrtanīyā drama and the expansion of the stage tradition

Maithili literary histories commonly treat kīrtanīyā drama as a major vernacular dramatic tradition. Works associated with authors such as Umāpati Upādhyāya show the continuing importance of songs, Sanskrit frames and vernacular theatrical expression. The Maithili Akademi edition of Umāpati’s Pārijātaḥaraṇa offers a concrete textual witness for studying this mixed dramaturgy. Dating individual authors and recensions requires caution, but the genre’s historical significance is clear: Maithili was capable of sustained theatrical organisation, not merely isolated songs inserted into Sanskrit drama. Kīrtanīyā performance also linked literary text to music, ritual and communal spectatorship. Through such traditions, the language acquired a stage canon whose social reach differed from both scholastic prose and private lyric.

37.25 Music, rāga and the memory of texts

A song text detached from melody is only part of the historical object. Rāga indications, performance lineages and recurring melodic frames can help stabilise lyric corpora, although musical practice itself changes over time. The connection to music also explains why some poems travel far beyond the political region where they were composed. A memorable melody can carry language into new courts, religious communities and households, while performers adapt pronunciation and vocabulary. This produces a paradox for textual history: wide circulation increases survival but also increases variation. Literary Maithili’s formation was strengthened by musical portability, yet the same portability makes the recovery of an “original” wording difficult. Editors therefore need to compare manuscript, oral and musical evidence rather than privilege one automatically.

37.26 Eastern circulation: Bengal, Assam and shared lyric worlds

Maithili lyric forms circulated through wider eastern Indian devotional and courtly networks. Later traditions in Bengal and Assam interacted with Maithili songs, while literary idioms such as Brajabuli drew prestige from an imagined or stylised Maithili-like language. These processes should not be represented as simple one-way “influence.” Songs, metres, devotional themes and authorial names moved through multilingual communities, often being adapted to new phonologies and audiences. The result can make attribution difficult: a text preserved in a Bengali or Assamese environment may reflect copying, translation, imitation or genuine transmission from Mithila. This wider reception nevertheless confirms Maithili’s

literary prestige. A language becomes regionally consequential when others choose to emulate or preserve its forms.

37.27 Canon formation accelerated under print and philology

The medieval archive did not organise itself into the canon familiar today. Nineteenth- and twentieth-century editors, antiquarians and linguists collected manuscripts, printed texts, classified scripts and assigned linguistic labels. George A. Grierson's 1881–82 introduction to Maithili, with grammar, chrestomathy and vocabulary, was foundational in making the language legible to modern comparative philology. Later histories by Jayakānta Mīśra and Radhakrishna Choudhary systematised literary periods and genres. This scholarship recovered enormous amounts of material, but it also created modern categories. “Early Maithili,” “medieval Maithili,” and author-centred canons are partly products of editorial decisions. A source-critical literary history must therefore study not only medieval composition but also the modern history of recovery. What survives in print is not a neutral mirror of what once circulated.

37.28 What counts as literary Maithili? an evidence firewall

Five questions should be kept separate. First, who is the author or attributed author? Second, when was the work composed? Third, when and where was the surviving manuscript copied? Fourth, what language or register does the text actually display? Fifth, how and when was it performed or canonised? Conflating these questions generates many chronological errors. A seventeenth-century copy can preserve a fourteenth-century text; a fifteenth-century author can write in Avahaṭṭa rather than Maithili; an orally transmitted song can be older than its first manuscript; a modern editor can standardise spelling. The evidence firewall does not make certainty impossible. It simply requires each claim to rest on the appropriate evidence class. This is especially important where celebrated names attract heterogeneous corpora.

EVIDENCE FIREWALL FOR EARLY MAITHILI LITERARY HISTORY

Strong claims require convergence across attribution, dating, manuscript, language and performance evidence.

Figure 147 — Evidence firewall for early Maithili literary history

37.29 A formation model: archive × performance × institutions × mobility

The formation of literary Maithili can be summarised as the interaction of four systems. Archive means texts that could be copied, stored and compared. Performance means songs and dramas that created

audiences and memory. Institutions mean courts, learned households, shrines and patronage networks that supplied resources and prestige. Mobility means the movement of people and texts among Mithila, Nepal, Bengal, Anga and other connected regions. None of the four alone is sufficient. A manuscript without readers may disappear; performance without recording may leave little datable evidence; patronage without a speech community cannot create vernacular intelligibility; local literature without mobility may remain regionally invisible. Literary Maithili became durable because these systems reinforced one another across centuries.

37.30 Conclusion: literary Maithili as a connected vernacular tradition

Literary Maithili emerged through vernacularisation inside a multilingual world. It drew on regional speech and oral performance, learned from Sanskrit and Middle Indo-Aryan literary traditions, gained visibility in works such as *Varṇa-ratnākara*, flourished in lyric and dramatic forms, and travelled through manuscript and performance networks into Nepal and wider eastern India. The process was cumulative rather than linear: Sanskrit remained strong, *Avahaṭṭa* remained available, and Persianate contact added another cosmopolitan layer. This chapter has also kept the volume's two-Vidyāpati framework intact rather than merging the pre-Jyotirīśvara Mahākavi's Maithili padāvalī corpus with the later fifteenth-century Vidyāpati Ṭhakkura's courtly Sanskrit/*Avahaṭṭa* works. Chapter 38 can now examine that distinction directly. For the broader social history, the essential point is already clear: Maithili became a literary language when communities could repeatedly compose, perform, preserve and recognise a regional vernacular across multiple genres and political spaces.

Table 37.1 — Formation of literary Maithili: major evidence and interpretive limits

Witness / evidence	Contribution	Secure use	Main caution
<i>Varṇa-ratnākara</i>	Early sustained prose; rich descriptive vocabulary	Shows elaborate Maithili prose	Stylised prose is not everyday speech
Jyotirīśvara's drama	Multilingual stage with vernacular functions	Shows Sanskrit, Prakrit and vernacular coexistence	Check language allocation in each recension
Mahākavi Vidyāpati padāvalī — project framework	Early lyric and performance stratum	Shows authority of vernacular song	Attribution and manuscript dating need testing
Later Vidyāpati Ṭhakkura	Fifteenth-century multilingual court corpus	Shows literary choice in Oiniwar culture	Do not merge with the Mahākavi lyric corpus
Nepal manuscripts / Malla drama	Cross-border preservation and theatrical prestige	Shows Maithili beyond Mithila	Many surviving copies are later than composition
Umāpati, Pārijātaharaṇa	Textual witness to Maithili drama	Useful for genre, song and stage language	Dating and recension history require caution
Grierson and later philology	Modern recovery, classification and print access	Documents canon formation	Modern taxonomy cannot be back-projected
Oral song traditions	Performance structures and remembered lyric	Shows non-manuscript continuity	Present wording cannot be dated automatically

Chapter 38 — The Two Vidyāpatīs and Two Historical Contexts

The name Vidyāpati stands at the centre of Maithili literary memory, but a name is not a chronology. This chapter follows the governing position adopted for this volume: it distinguishes an earlier Mahākavi Vidyāpati, treated as the pre-Jyotirīśvara poet of the Maithili Padāvalī tradition, from the later Vidyāpati Ṭhakkura associated with the Oiniwar-period courtly and learned world and with Sanskrit and Avahaṭṭa works such as Kīrtilatā, Kīrtipatākā, Puruṣaparīkṣā, Gorakṣavijaya and Likhanāvalī. Because most modern scholarship combines these corpora within a single fifteenth-century biography, the distinction used here must be argued methodologically rather than asserted as consensus. The task is therefore to keep composition, manuscript transmission, patronage, language, genre and later reception separate, and to ask where the evidence genuinely converges.

38.1 The historiographical problem: one celebrated name, several archives

Literary history often begins with the author-name printed on a modern title page and works backward. That method is hazardous for premodern South Asia, where texts circulated in manuscripts, anthologies, performance lineages and scribal copies long before modern critical editions. “Vidyāpati” can therefore function simultaneously as a historical personal name, an authorial signature, a prestige attribution, a lineage of reception and a later canonical umbrella. The central problem is not whether tradition is valuable; it is how to disaggregate the kinds of evidence that tradition carries. A lyric transmitted in a Nepalese anthology, a Sanskrit legal treatise with a courtly frame, and an Avahaṭṭa political narrative do not become coeval merely because later scholarship places them under one name.

38.2 The project’s adopted two-Vidyāpati framework

This volume adopts a two-profile model. The first profile is Mahākavi Vidyāpati, placed before Jyotirīśvara and associated primarily with Maithili Padāvalī lyric. The second is the later Vidyāpati Ṭhakkura, situated in the fifteenth-century political and scholastic environment of Mithila and associated with the Oiniwar court, Sanskrit learning and Avahaṭṭa political writing. This is an interpretive position of the present project, not a claim that standard scholarship has already settled the matter in this way. The value of the model lies in the discipline it imposes: each corpus must earn its chronology through its own linguistic, codicological, historical and intertextual evidence rather than through inherited authorial aggregation.

38.3 Conventional scholarship and why it must be represented fairly

Most twentieth- and twenty-first-century scholarship treats Vidyāpati Ṭhākura as a single multilingual intellectual active broadly in the fourteenth and fifteenth centuries. Subhadra Jha’s edition of the songs, Radhakrishna Choudhary’s historical synthesis, the Sahitya Akademi tradition, Christopher Diamond’s manuscript study and Pankaj Jha’s political-literary history all work, with different emphases, within a single-author frame. A source-critical alternative must acknowledge that fact. The argument for separation cannot rest on ignoring conventional scholarship; it must explain why certain chronological, generic or transmission problems remain visible even after the single-author model is granted its strongest evidence.

38.4 A hierarchy of evidence

For this chapter, evidence is ranked rather than merely accumulated. Dated inscriptions, colophons and documentary formulas have the strongest chronological force when their authenticity and reading are secure. Explicit patronage references and identifiable political events provide a second layer. Linguistic register and genre can distinguish literary worlds but rarely date a text by themselves. Manuscript provenance gives a terminus for the surviving witness, not automatically for original composition. Bhaṇitā signatures and later attributions are important but must be tested against anthology history. Oral continuity and cultural memory are indispensable for reception history, yet they are least suited to precise absolute dating without corroboration.

Figure 148 — *Two Vidyāpatīs: evidentiary profiles in this volume*

38.5 Mahākavi Vidyāpati: the earlier lyric profile in this volume

Within the adopted framework, Mahākavi Vidyāpati belongs to an earlier Maithilī lyric horizon, prior to Jyotirīśvara. The defining evidence is not a court list but a poetic ecology: compact padas, musicality, voice, erotic-devotional intensity, recurring emotional situations and a language adapted to performance and memorisation. The profile is therefore reconstructed through lyric form, the history of song transmission and the internal life of the Maithilī vernacular. The absence of a bureaucratic documentary frame is itself significant. This profile should not be forced into the later Oiniwar political sequence merely because the same prestigious name appears in subsequent literary history.

38.6 “Pre-Jyotirīśvara” as a chronological claim that requires discipline

To call Mahākavi Vidyāpati pre-Jyotirīśvara is stronger than calling the songs “old.” It places the lyric horizon before the early-fourteenth-century textual world associated with Jyotirīśvara and Varṇa-ratnākara. Such a claim must therefore remain tied to the project’s specific reading of Panji, literary and manuscript evidence. It should not be converted into invented birth and death dates. Where no secure dated witness exists, the responsible language is relative chronology: earlier than, later than, contemporary with, or transmitted after. The chapter consequently refuses to fill chronological gaps with rounded dates that merely look authoritative.

38.7 Padāvalī as a performance corpus rather than a single authored book

A padāvalī is not necessarily a book designed once and preserved unchanged. It is a corpus of songs that may circulate independently, be recombined by singers and scribes, acquire rāga labels, shift sequence and enter anthologies alongside other poets. The historical object is therefore plural. One must distinguish an individual pada, a local repertory, a manuscript collection, a later printed Padāvalī and the modern idea of a fixed authorial oeuvre. This matters directly to the two-Vidyāpati problem because the apparent unity of a printed collection may be a product of editorial history rather than a transparent mirror of the earliest compositional moment.

38.8 The Nepal manuscript tradition and what it can actually prove

The Nepal manuscript tradition is crucial because it preserves an early and influential corpus of songs attributed to Vidyāpati. Subhadra Jha’s twentieth-century scholarship treated the Nepal manuscript as a major textual witness, and later manuscript studies have emphasised its importance for tracing anthology history. Yet a manuscript date and a composition date are not identical. The witness proves that a body of songs, with particular attributions and textual forms, existed by the time of that copy. It does not by itself tell us how many generations of oral or written transmission preceded it, nor whether every attributed pada entered the corpus at the same time.

38.9 Bhaṇitā, signature and the danger of circular attribution

The poet-name inside a lyric is important evidence, but it is not infallible. In South Asian devotional and courtly traditions, famous signatures could be imitated, preserved formulaically, added by scribes or transferred through oral memory. A modern editor who selects all verses bearing “Vidyāpati” and then uses the resulting collection to prove a single author risks circular reasoning. The better procedure is comparative: examine linguistic form, metre, thematic clusters, manuscript distribution, variant readings and the age of each witness. Attribution becomes stronger when several independent indicators converge; it becomes weaker when a signature is the only link.

Chronology without forced conflation

Figure 149 — Chronology without forced conflation

38.10 Lyric language and the problem of later normalisation

Manuscripts and printed editions can normalise spelling, morphology and vocabulary. A song copied centuries after its composition may therefore look linguistically younger than its core, while an editor seeking archaism may produce the opposite effect. The language of the Padāvalī must be studied at the level of variant witnesses, not only from modern standardised editions. This is particularly important for an earlier Mahākavi hypothesis. If the argument depends on linguistic archaism, it must identify forms that survive across independent witnesses and distinguish them from scribal convention, metre-driven variation, later Brajabuli adaptation and editorial regularisation.

38.11 Erotic, devotional and domestic voices as a distinct literary world

The lyric corpus attributed to Mahākavi Vidyāpati moves through longing, separation, union, jealousy, persuasion, seasonal change and devotional transvaluation. Its dramatic energy often depends on female personae, messengers and intimate dialogue. This world is socially dense but institutionally light: it evokes bodies, houses, roads, seasons, ornaments, ritual occasions and emotional codes rather than the machinery of courts, charters and legal procedure. Genre alone cannot prove different authorship, but the contrast establishes a historical question. If two corpora inhabit sharply different social worlds, their unity should be demonstrated, not merely presumed.

38.12 Reception in Bengal, Assam and Nepal is not evidence of original date

The immense eastern Indian afterlife of the songs is one reason the name Vidyāpati became larger than any single manuscript. Bengal developed Brajabuli lyric under Vidyāpati's influence; Assamese and Nepalese performance cultures also received Maithili forms. Reception, however, can telescope time. A fifteenth- or sixteenth-century community may preserve, transform or newly attribute older material. Conversely, a later imitation may look archaic because it deliberately adopts a prestigious style. The geographical spread of a corpus therefore proves literary authority and mobility, but chronology must still be established through independent anchors.

38.13 Transition to the later Vidyāpati Ṭhakkura profile

The later profile is different in evidentiary character. Here the archive becomes unusually documentary: named rulers, political conflict, learned Sanskrit genres, administrative correspondence, moral instruction and Avahaṭṭa political narrative. Pankaj Jha's work demonstrates how much fifteenth-century social and political history can be extracted from Likhanāvalī, Puruṣaparīkṣā and Kīrtilatā when they are read in their courtly context. This is precisely why the profile should be analysed on its own terms. It possesses chronological anchors and institutional textures that do not need to be borrowed from the lyric corpus.

38.14 Oiniwar Mithila as the later historical setting

The later Vidyāpati Ṭhakkura is placed within the fragmented but intellectually vibrant political landscape of fifteenth-century Mithila, where local rulers negotiated with neighbouring powers, especially the Sharqi world of Jaunpur, and where Sanskrit scholastic authority coexisted with vernacular and Persianate currents. Court patronage created occasions for praise, political biography, legal reasoning, ritual compilation and documentary instruction. This environment is not a mere backdrop: it explains why one learned writer might move among Sanskrit, Avahaṭṭa and practical documentary genres. The later profile is therefore tied to institutions as much as to literary style.

38.15 Kīrtilatā: Avahaṭṭa political biography and connected worlds

Kīrtilatā is central to the later profile because its language and politics belong to a connected North Indian world. Modern scholarship describes it as an Avahaṭṭa or Apabhraṃśa-register political biography concerned with the fortunes of Kīrttiśiṃha and with the wider power field in which Mithila operated. Its vocabulary includes Sanskritic and Persianate elements; its political imagination moves beyond a sealed regional culture. In this volume, Kīrtilatā therefore belongs to Vidyāpati Ṭhakkura's fifteenth-century corpus. It should not be used automatically to date the earlier Maithili lyric profile unless an independent textual bridge is demonstrated.

38.16 Kīrtipatākā and the limits of surviving evidence

Kīrtipatākā is also associated with the later Vidyāpati Ṭhakkura tradition, but its textual history demands caution. Premodern works often survive incompletely, in late copies, or through editorial reconstruction. A title known from literary histories may have a weaker manuscript basis than a dated documentary text. The methodological point is larger than this single work: corpora should not be treated as equally secure simply because modern bibliographies list them side by side. Each text requires its own stemma of witnesses, dates, citations and editorial interventions.

38.17 Puruṣaparīkṣā: Sanskrit political ethics and social hierarchy

Puruṣaparīkṣā belongs to the Sanskrit learned world of the later profile. Pankaj Jha reads it as a work of political ethics and masculinity that uses narrative to educate and entertain while embedding ideas of statecraft, gender and hierarchy. Its intellectual genealogy reaches into classical Sanskrit traditions even as its concerns are made contemporary. The work therefore provides evidence for the social imagination of fifteenth-century elite culture in Mithila. It is methodologically distinct from the Padāvalī: similarities of moral vocabulary or devotional reference cannot erase differences of genre, audience, institutional function and transmission.

38.18 Likhanāvalī: writing, administration and the c. 1418 horizon

Likhanāvalī is one of the strongest chronological anchors for the later profile. The exemplary documents in the work are dated in Lakṣmaṇa Era 299, corresponding approximately to 1418 CE, and scholarship places the text in the milieu of Purāditya and the period of political displacement associated with Śivasīṃha's fall. The work models official and private letters, transactions and social communications. This gives the later Vidyāpati Ṭhakkura a concrete documentary horizon. The strength of this anchor also clarifies the central problem: it dates Likhanāvalī and its context securely; it does not automatically date every lyric later attributed to the same name.

Composition, manuscript and reception are different dates

Figure 150 — Composition, manuscript and reception are different dates

38.19 The 1428 Bhāgavata copy as a material chronological witness

An important later chronological anchor is the manuscript copy of the Bhāgavata associated with Vidyāpati and dated to Lakṣmaṇa Era 309, approximately 1428 CE. Older chronological studies, including Muhammad Shahidullah's analysis, used this kind of dated material to reconstruct the life of the conventional single Vidyāpati. Within the two-profile model, the evidence is retained but assigned more narrowly: it establishes the activity of the later Vidyāpati Ṭhakkura profile in the fifteenth century. It should not be made to pull an undated lyric corpus forward in time without an explicit chain of evidence connecting the two.

38.20 Gorakṣavijaya and the problem of multilingual dramatic attribution

Gorakṣavijaya, associated in this project with the later Vidyāpati Ṭhakkura, reminds us that dramatic and performative texts can themselves be multilingual and unstable in transmission. A play may contain Sanskrit framing, vernacular songs, stage-language conventions and later interpolations. Its attribution must therefore be tested through manuscripts and performance history rather than genre labels alone. The existence of vernacular elements in a later courtly drama cannot be used as a shortcut to merge it with the earlier Padāvalī poet. Multilingual competence is historically plausible for the later profile, but plausibility is not identity proof.

38.21 One person can write in many languages—but that is not the whole argument

The strongest objection to separating the corpora is straightforward: multilingual authorship was normal in premodern India. A Sanskrit scholar could compose Avahaṭṭa narrative and Maithili song; language difference therefore cannot by itself prove two authors. This chapter accepts that objection. The two-Vidyāpati model does not rest on language alone. It rests on a bundle of questions: relative chronology, genre ecology, manuscript transmission, political anchoring, patterns of attribution and the gap between performance archive and courtly documentary archive. Only the cumulative pattern can sustain separation; no individual linguistic feature is sufficient.

38.22 Nor does genre difference alone prove two authors

A prolific author can write love lyrics, political praise, legal manuals and devotional works. Genre diversity is therefore evidence of range, not automatically of multiplicity. The historical question is whether the genres share demonstrable chronological bridges. Do securely dated manuscripts cross-reference one another? Do early witnesses attribute both corpora to the same person? Do patrons, family relations or colophons connect them? Do lexical and metrical fingerprints remain stable enough across languages to matter? By asking these questions, the two-profile framework becomes testable. Without such tests, separation would be no more rigorous than conflation.

38.23 Namesakes, titles and prestige attribution in learned cultures

“Vidyāpati” itself carries semantic prestige: lord or master of knowledge. Premodern learned cultures frequently contain repeated personal names, honorifics, lineage names and titles. A later scholar may bear the same name as an earlier poet without deception or confusion in his own time; conflation can arise only when later catalogues compress distinct archives. Conversely, an honorific can become attached to a famous individual and make genuine continuity more likely. The name therefore has evidentiary value, but its weight must be calibrated against dates, genealogy and manuscript provenance. Onomastic identity is a clue, not a verdict.

38.24 Why later canon formation encourages conflation

Print culture prefers stable authors and collected works. Editors, academies and literary histories have understandable reasons to gather dispersed texts under a celebrated name: readers gain a coherent oeuvre, regional literature gains a representative genius, and manuscripts become easier to catalogue. But the resulting author can be more unified than the premodern archive ever was. The same process is visible across world literatures where anonymous, pseudonymous and composite traditions later crystallise around major names. The task of critical history is not to dismantle cultural reverence; it is to distinguish the history of the canon from the history of composition.

38.25 The two biographies as different social histories

If separated, the two Vidyāpati profiles illuminate different phases of Mithila’s cultural history. Mahākavi Vidyāpati represents the deep vernacularisation of lyric and performance: speech becoming song, song becoming portable literary memory, and intimate voices becoming transregional cultural capital. Vidyāpati Ṭhakkura represents a later world of courtly negotiation, Sanskrit intellectual authority, Avahatṭa political narrative, administrative writing and contact with Persianate state forms. The distinction therefore has consequences beyond literary biography. It allows two different social formations to remain historically visible instead of being compressed into the life of a single exceptional polymath.

38.26 The implications for Jyotirīśvara and early Maithili chronology

The adopted chronology also changes the position of Jyotirīśvara. In a conventional single-Vidyāpati narrative, Jyotirīśvara appears as an important predecessor to a fourteenth/fifteenth-century Vidyāpati. In this project, the earlier Mahākavi Vidyāpati precedes Jyotirīśvara, making the Padāvalī horizon part of the deeper prehistory of literary Maithili. Varṇa-ratnākara then becomes not the beginning of the language but an early surviving prose monument within an already developing vernacular world. This is a major historiographical consequence and therefore requires especially careful source separation, not rhetorical certainty.

38.27 The implications for Maithili literary periodisation

Periodisation built around a single “Age of Vidyāpati” risks absorbing too much. The two-profile model encourages a more granular sequence: an earlier lyric/performance horizon; the early-fourteenth-century prose and dramatic world of Jyotirīśvara; a fifteenth-century courtly and scholastic horizon associated with Vidyāpati Ṭhakkura; and later manuscript, devotional and theatrical expansions across Nepal and eastern India. Such periodisation better accommodates discontinuity. It also allows literary forms to overlap without forcing them into a linear ladder from primitive vernacular to mature literature.

38.28 An attribution firewall for this volume

Future chapters will apply an explicit firewall. A work will not be assigned to Mahākavi Vidyāpati merely because it is in Maithili, nor to Vidyāpati Ṭhakkura merely because a modern edition prints his name. Attribution should specify the evidence category: early manuscript, later manuscript, *bhaṇitā*, colophon, external citation, court reference, linguistic comparison or modern editorial tradition. Where the evidence is mixed, the text will be described as “attributed to” rather than silently absorbed. This protects both profiles from accumulating works by inertia and makes later correction possible if stronger manuscript evidence appears.

Figure 151 — Evidence firewall for Vidyāpati attribution

38.29 What evidence could falsify or revise the two-profile model?

A historical model should identify what could prove it wrong. A securely dated early manuscript that unambiguously links the Padāvalī poet with the later courtly genealogy would strongly weaken the separation. Conversely, an early witness explicitly distinguishing two Vidyāpatīs would strengthen it. A demonstrable chain of self-citation across securely dated works would also matter. So would palaeographic or codicological evidence that moves key lyric witnesses earlier or later. The project’s position is therefore provisional in the scholarly sense: adopted consistently because it best fits the present internal framework, but open to revision by superior primary evidence.

38.30 Conclusion: preserve difference until evidence justifies identity

The safest principle is asymmetrical: similarity should invite comparison, but identity should require convergence. This volume therefore preserves two Vidyāpatīs because doing so prevents the dated fifteenth-century documentary archive from colonising an earlier lyric chronology by assumption. Mahākavi Vidyāpati remains the pre-Jyotirīśvara Maithili Padāvalī poet in the project’s framework; Vidyāpati Ṭhakkura remains the later Oiniwar-associated Sanskrit/Avahatṭa intellectual and courtly writer. Conventional single-author scholarship is recorded and engaged rather than erased. The resulting history is less tidy than a single heroic biography, but it is more transparent about what each category of evidence can and cannot prove.

Table 38.1 — Two Vidyāpati profiles: evidence domains and cautions

Evidence domain	Mahākavi Vidyāpati — project profile	Later Vidyāpati Ṭhakkura — project profile	Main caution
Relative chronology	Pre-Jyotirīśvara lyric horizon	Fifteenth-century/Oiniwar-associated horizon	Do not invent exact dates where only relative chronology is available
Core corpus	Maithili Padāvalī lyric tradition	Kīrtilatā, Kīrtipatākā, Puruṣaparīkṣā, Likhanāvalī, Gorakṣavijaya and related learned works	Modern collected editions may over-unify transmission
Primary registers	Maithili lyric and performance language	Sanskrit and Avahatṭa, with multilingual courtly context	Language difference alone cannot prove different authors
Social setting	Performance, song, intimate and devotional lyric worlds	Court, administration, political ethics, scholastic and documentary worlds	Genre difference alone cannot prove different authors
Manuscript evidence	Anthologies and lyric witnesses, including Nepal transmission	Dated/documentary and learned manuscript contexts	Copy date is not automatically composition date
Chronological anchors	Project’s relative pre-Jyotirīśvara placement	c. 1418 Likhanāvalī horizon; c. 1428 Bhāgavata copy witness	Anchors date specific evidence, not every attributed work
Reception history	Wide eastern circulation; later Brajabulī and devotional prestige	Historical and scholarly consolidation into a polymath court-author profile	Reception can create retrospective unity
Attribution rule	Require convergence beyond name or bhaṇitā	Require convergence beyond modern bibliographic assignment	Use “attributed to” where evidence remains mixed

Chapter 39 — Tirhuta/Mithilakshar and Scribal Culture

Tirhuta, also called Mithilakshar and historically “Maithili” script in some descriptions, belongs to the eastern Brahmi-derived family of writing systems. Yet the social history of the script cannot be reduced to an alphabet chart. Its significance lies in the manuscript worlds that connected Sanskrit and Maithili learning, household archives, teachers and pupils, legal and ritual texts, lyric anthologies, Nepalese repositories, correspondence and later movements of print and digital revival. This chapter therefore separates palaeographic ancestry from a fixed script identity, script from language, composition from surviving copy, and manuscript culture from modern claims about a single community. The aim is to reconstruct Tirhuta as a changing technology of knowledge and social memory.

39.1 Script history requires palaeography, not retrospective naming

Writing systems change gradually. Later observers often attach a familiar name to every earlier regional hand that resembles it, but palaeography works more cautiously. Tirhuta belongs to an eastern line of Brahmi-derived scripts associated with Kuṭṭila and Gauḍī developments, and it is closely related to Bengali-Assamese, Newar and Odia traditions. The Unicode Standard describes these related scripts as differentiated branches rather than identical forms extending unchanged into antiquity. For social history this distinction matters: an early eastern inscription can illuminate ancestry without proving that contemporaries understood its hand as the same scribal system later called Tirhuta or Mithilakshar. The historical question is therefore when a recognisable regional convention became stable enough to support recurring scribal practices, not how far backward a modern name can be projected.

39.2 Tirhuta, Mithilakshar and “Maithili script” are overlapping names

The script has circulated under several names. “Tirhuta” refers to the Tirhut/Mithila region; “Mithilakshar” literally marks the letters of Mithila; and “Maithili script” has also appeared in scholarship and encoding discussions. The 2006 Unicode roadmap request explicitly noted that all three names were historically attested and used interchangeably, while later standardisation adopted “Tirhuta” as the formal script name. The multiplicity of names should not be mistaken for multiple unrelated scripts. At the same time, nomenclature carries politics: naming a script after a language emphasises linguistic ownership, while naming it after a region can accommodate its use for Sanskrit and other learned purposes. This volume therefore uses Tirhuta/Mithilakshar as paired historical designations.

39.3 Script and language must be kept separate

A script is a graphic technology, not a language. Tirhuta has been used for Maithili, but manuscript traditions also used it for Sanskrit. Conversely, Maithili has been written in more than one script, including Devanagari, Kaithi and Newar hands in different places and periods. Confusing script with language creates false conclusions: a Sanskrit manuscript in Tirhuta does not become Maithili literature, and a Maithili text copied in Devanagari does not lose its linguistic identity. Scribal culture is therefore best analysed through a matrix of language, script, genre, material and institutional setting. Such a matrix also helps explain why a regional script could remain socially meaningful even while multilingual scholars moved between Sanskrit and vernacular registers.

39.4 From Gauḍī-related ancestry to a differentiated medieval hand

The Unicode core specification places Tirhuta within the Gauḍī-derived eastern family and states that differentiation from related scripts was established by the fourteenth century. This is a safer chronological threshold for a distinct scribal identity than claims that every much earlier eastern form is already Tirhuta in its later shape. Letterforms do not change simultaneously, and scribes can retain archaic habits or adopt features from neighbouring traditions. Boundaries between scripts are therefore historical gradients. By the medieval period, however, a recognisable regional hand could support sustained scholarly and religious manuscript production in Mithila. The emergence of such a convention reflects networks of training: scribes learned not isolated characters but repertoires of ligatures, abbreviations, page architecture and correction practices.

Figure 152 — *Tirhuta: palaeographic ancestry is not the same as a fixed script identity*

39.5 A manuscript is an artefact, not merely a container of words

To read scribal culture historically, the manuscript must be treated as a physical object. Palm leaf and paper impose different constraints on line length, folio shape, binding, margins and repair. Ink density, ruling, foliation, worm damage, replacement leaves and later bindings can preserve a biography of use. A modern transcription strips away most of this evidence. Two printed editions may present the same passage identically even if their manuscripts were separated by centuries, copied in different regions and corrected by different hands. Codicology therefore complements textual criticism: the scholar asks what the object was made from, how quires or leaves were organised, where the scribe placed headings, how corrections were inserted, and what later readers added.

39.6 The scribe as a historical actor

Premodern scribes were not neutral copying machines. They selected exemplars, resolved illegible forms, regularised spelling, omitted or repeated passages, inserted glosses and sometimes identified patrons, teachers or dates in colophons. Their choices can preserve dialectal features or erase them. A copying error may expose the visual similarity of two letterforms; a correction may reveal that a second reader checked the text. Scribal agency is especially important for Maithili literary history because many works survive only through later witnesses. The scribe stands between composition and the surviving artefact. Instead of treating variation as

corruption alone, historical analysis can ask what forms of literacy, memory and pedagogy produced the variation.

39.7 Patronage, commission and the household archive

Manuscripts entered social life through commissions, gifts, inheritance and institutional copying. A patron might finance a religious text, a legal digest, a ritual manual or a literary work for study and prestige. Households could preserve genealogical, legal and ceremonial records alongside scholastic manuscripts. The continued association of Tirhuta with ceremonial correspondence, including marriage-related letters in some communities, shows how script could mark a social occasion even after everyday writing shifted elsewhere. Yet such later specialised use must not be projected backward as proof that medieval Tirhuta belonged exclusively to one caste or ritual group. The archive visible today is shaped by survival: durable elite collections are more likely to be preserved than the writing practices of poorer or less institutionalised users.

39.8 Scholastic culture: copying as study

In centres of Sanskrit learning, copying could be a form of education. A manuscript of logic, grammar, ritual, philosophy or law was not merely stored; it was read aloud, explained, annotated and recopied. Marginal notes and interlinear additions can therefore register pedagogical encounters. Mithila's intellectual history, including Navya-Nyāya and Dharmaśāstra traditions, depended on such manuscript labour. Tirhuta's importance here lies not in an exclusive script-language bond but in its role within a regional scholarly ecology. The same learned person could read Sanskrit in Tirhuta, compose or perform Maithili, and encounter Devanagari or other eastern scripts. Multiscript competence was an asset rather than an anomaly.

Figure 153 — *The manuscript as a scribal ecosystem*

39.9 Colophons: valuable anchors with limits

Colophons can record the completion of copying, the scribe, patron, place, teacher, owner or date. They are among the strongest internal anchors for manuscript history, but they must be interpreted precisely. A dated colophon normally dates the copy in which it appears, not automatically the original composition. A scribe may reproduce an older colophon from the exemplar or add a new one. Calendrical conversion can introduce additional uncertainty. Chapter 38 used this rule for Vidyāpati attribution; the same firewall

applies here. Script history gains when palaeography, material features and colophon information converge. When they conflict, the conflict is evidence requiring explanation, not an inconvenience to be harmonised away.

39.10 Letterforms, ligatures and scribal hands

Palaeographic comparison examines more than isolated alphabet samples. Useful features include the treatment of vowel signs, conjunct consonants, headline behaviour, terminal strokes, numeral forms, punctuation, spacing and the relative proportions of letters. Individual scribes develop habits, while workshops and teaching lineages can produce families of hands. A script chart necessarily idealises this variation. Historical Tirhuta manuscripts therefore should not be judged by whether every character matches a modern font. Digital standardisation encodes characters, whereas manuscripts display glyph variation. The distinction between character and glyph is essential when old forms are mapped into Unicode or when a palaeographer decides whether an unusual shape is a distinct sign, a ligature or simply a scribal variant.

39.11 Numerals, accounting signs and everyday literacy

The social life of a script extends beyond literary pages. North Indian accounting signs and number forms circulated across several scripts, including traditions associated with Tirhuta. Such shared signs remind us that scribal boundaries were permeable. Merchants, administrators and household accountants could use repertoires different from those of a scholastic manuscript. Everyday writing is often underrepresented because ephemeral papers were discarded. The surviving literary canon therefore cannot by itself measure the full social range of literacy. Where accounting or legal documents survive, they should be studied alongside formal manuscripts to reconstruct the interaction between learned and practical hands.

39.12 Correction, omission and the archaeology of copying

Corrections reveal how manuscripts were made. A scribe may strike through a word, place a replacement above the line, insert omitted material in a margin or mark the place where a later leaf should be read. Repeated lines can result from the eye returning to the wrong occurrence of a similar phrase; omissions can occur when it jumps forward. Such errors are not random noise. They help textual critics infer relationships among copies and help historians see the mechanics of reading. In a lyric anthology, missing stanzas or irregular rhyme may suggest scribal omission; in a legal text, a marginal supplement may signal active comparison with another exemplar. Manuscript variation is therefore evidence of circulation.

39.13 The Nepal repositories and the preservation of Maithili materials

Nepal is indispensable to the history of Maithili manuscripts. Political, dynastic and cultural contacts carried texts, performers and scribal practices across the Himalayan foothill corridor. Important Maithili dramatic and lyric materials survive in Nepalese collections, sometimes in scripts or hands related to Mithila's own traditions. The so-called Nepal Manuscript of Vidyapati songs, for example, is written in the Maithili/Tirhuta script and has served as a major witness for twentieth-century editors. Its importance is precisely that of a manuscript witness: it provides a chronological and textual waypoint, not an automatic date for the composition of every poem it contains. Preservation geography must be distinguished from composition geography.

39.14 Manuscript anthologies and the problem of attribution

An anthology brings together texts that may have originated at different times and places. The compiler's decisions shape what later readers understand as a corpus. A name in a bhaṇitā or heading is evidence, but the manuscript context must be assessed: was the label written by the main scribe, a later hand or an editor? Did the exemplar already contain it? Are other poets represented? Chapter 38's two-Vidyāpati model makes these questions especially important. Tirhuta manuscripts can preserve early lyric traditions while still being later copies. Script alone cannot decide authorship. The proper unit of analysis is the complete witness: hand, material, sequence, attribution, variants and later annotations.

Figure 154 — Four evidence layers in manuscript analysis

39.15 Tirhuta and the legal-documentary world

Mithila's manuscript culture included legal, ritual and administrative genres, not just poetry. Learned digests, letters, genealogical materials and practical documents created recurrent demand for trained writing. The later Vidyāpati Ṭhakkura's Likhanaṁālī belongs to a documentary imagination in which formula, address, social relation and written authority matter. Even when particular surviving copies use another script, the broader culture of formal writing helps explain why regional scribal expertise was socially valuable. Written documents could stabilise memory, encode hierarchy and travel beyond the immediate speaker. Yet documentary authority should not be romanticised: access to trained scribes and archives was uneven, and oral testimony continued to coexist with written forms.

39.16 Tirhuta and Panji: connection without total identification

The Panji tradition discussed in Chapter 31 depended on genealogical recording and specialist custodianship, and Tirhuta has been associated with such manuscript practices. But the two institutions should not be collapsed. Panji is a genre and archival-social institution; Tirhuta is a script. Genealogies can be recopied in other scripts, and Tirhuta was used for many texts unrelated to Panji. The methodological value of separating them is chronological as well as social. A later Panji manuscript may preserve older genealogical claims, while its handwriting reflects the date of copying. Likewise, later classifications within Panji cannot be pushed backward merely because the manuscript is written in a traditional script.

39.17 Sanskrit in Tirhuta: regionality without vernacularity

A Sanskrit text written in Tirhuta demonstrates how cosmopolitan language and regional script could coexist. This pairing complicates the common modern assumption that one language naturally belongs to one script. Sanskrit scholars in Mithila could participate in a pan-Indian intellectual language while using a regionally characteristic hand. The manuscript thereby carried two scales of identity at once: transregional Sanskrit learning and local scribal formation. This is important for the social history of knowledge. Regionalisation did not require abandoning Sanskrit; rather, local institutions could domesticate a cosmopolitan language through their own graphic practices, teaching lineages and archives.

39.18 Maithili in Tirhuta: vernacular text and visual region

When Maithili is written in Tirhuta, language and regional script reinforce one another, but even here the relationship is historical rather than timeless. Literary Maithili developed through oral, performative and manuscript channels; some witnesses use Tirhuta, others other scripts. A Tirhuta manuscript can nevertheless create a strong visual sense of regional belonging because readers recognise both the language and the graphic tradition. This visual identity became especially significant when print increasingly favoured Devanagari. The older script could then be remembered not merely as a tool but as a symbol of the manuscript age and of a distinctive Maithili public past.

39.19 Scribal multilingualism and mixed textual environments

Manuscripts often inhabit multilingual environments. A Sanskrit verse may accompany a Maithili explanation; a vernacular dramatic text may contain Sanskrit formulae; a title, colophon or ownership note may use a different register from the main body. Script does not necessarily change when language changes. Such mixed environments are crucial evidence against rigid modern language boundaries. They show readers moving across registers according to function. A scribe trained in Tirhuta could therefore mediate between scholastic Sanskrit, vernacular literary forms and practical notation. The manuscript page becomes a site where linguistic hierarchy and everyday multilingual competence meet.

39.20 From palm leaf to paper: material transition and scribal possibilities

The spread of paper did not instantly abolish palm-leaf manuscript culture, but it altered the economics and physical possibilities of copying. Paper could permit different page proportions, denser writing, easier binding and new patterns of annotation. Material transitions may also change which genres are copied and how often. A text recopied onto paper can survive after earlier palm-leaf exemplars disappear, making the later medium appear falsely original. Social historians should therefore resist equating the age of the surviving material with the age of the work. The sequence of media is part of transmission history.

39.21 Archives, loss and the survival bias of literary history

What survives is not a random sample of what once existed. Manuscripts preserved in royal, monastic, scholarly or landed households have a better chance of reaching libraries than ephemeral notes or the papers of marginal groups. Climate, insects, flooding, political upheaval, sale and neglect further filter the archive. Tirhuta's surviving corpus may therefore overrepresent learned and ritual traditions. Claims about who "used" the script must be framed as claims about attested use, not total historical use. The absence of manuscripts from a community can mean non-use, but it can also mean non-preservation. A source-critical history makes this survival bias visible.

39.22 Print did not simply replace manuscripts overnight

The arrival of print transformed reproduction, but manuscript and print coexisted for long periods. Printed books lowered the cost of producing identical copies and favoured scripts for which type, compositors and markets were available. Manuscripts remained useful for ritual, private correspondence, local archives and texts outside commercial demand. In Maithili, the eventual dominance of Devanagari in print changed the balance between graphic traditions. The shift should not be narrated as technological inevitability alone. Font availability, printing infrastructure, education, language politics and the economics of readership all influenced which script became convenient for publishers.

39.23 Devanagari and the remaking of modern Maithili print

Mithilesh Kumar Jha notes that early modern Maithili periodicals increasingly used Devanagari and points to the absence of adequate Mithilakshar type, familiarity with Nagari among scholars and the wider Nagari movement as possible factors. Recent scholarship further argues that the transition from manuscript to print reshaped the social image of Maithili itself. The point for this chapter is not to treat Devanagari as foreign or Tirhuta as a frozen essence. Rather, script choice became part of modern institution-building. A language could expand its print readership through one script while losing routine competence in another. The social cost was a growing distance between modern readers and older manuscript archives.

39.24 Metal type, fonts and the problem of graphic standardisation

Movable type requires decisions that manuscript writing can postpone. A punchcutter or font designer must define a finite inventory of characters and ligatures, regularise proportions and decide how conjuncts will be produced. Manuscript Tirhuta contains variation that does not map neatly onto a single typeface. Early type and later digital fonts therefore represent acts of interpretation. They make the script reproducible but also select particular glyph norms. The historical manuscript should never be judged as “incorrect” because it differs from a modern font. Standardisation is a new layer in the script’s history.

39.25 Unicode: characters, not a digital facsimile of every manuscript hand

Tirhuta was encoded in Unicode 7.0 in 2014 and occupies the block U+11480–U+114DF. Encoding is crucial because it allows text to be stored as interoperable characters rather than image fragments or private font hacks. Yet Unicode does not preserve every historical glyph. It encodes an abstract character repertoire and rendering rules; fonts supply visual forms. Scholars digitising manuscripts must therefore distinguish transcription from facsimile. A Unicode transcription can make a text searchable and comparable, while page images preserve the precise ductus, spacing, damage and scribal variants. The strongest digital edition links both.

39.26 Revitalisation and the new social life of Tirhuta

Unicode encoding, fonts, keyboards, teaching material and public signage have given Tirhuta a new technological environment. Government committees and literary organisations have supported preservation and instruction, while enthusiasts use the script in digital communication. Revival, however, is not simple restoration. Modern learners often encounter a standardised font before seeing manuscripts; digital input methods may favour forms different from historical handwriting. The revived script therefore enters a new social world. This does not diminish authenticity. It demonstrates that scripts survive by changing functions—from manuscript technology to heritage marker, educational subject and digital writing system.

Figure 155 — From manuscript circulation to print and digital encoding

39.27 Accessibility to the manuscript archive

A script can become culturally prestigious at the same moment that fewer people can read it. This creates an archival bottleneck: large bodies of regional history may remain effectively closed to speakers of the language whose past they record. Preservation must therefore include cataloguing, high-resolution imaging, palaeographic training, transliteration and searchable transcription. Devanagari editions can widen access, but they should retain links to the Tirhuta witness so that editorial choices are auditable. Accessibility also means metadata: date, provenance, material, dimensions, folio sequence and scribal notes should accompany digital images rather than being stripped away.

39.28 A source-critical workflow for Tirhuta manuscripts

This volume adopts a simple workflow. First identify the physical witness and repository. Second describe material, foliation, hand and script without assuming a composition date. Third transcribe the text while recording uncertain readings. Fourth distinguish main text from marginalia, colophon and later additions. Fifth compare parallel witnesses where available. Sixth assign dates only to the specific evidence that supports them. Seventh separate script history from claims about language, caste or authorship. This workflow turns the manuscript from an illustration into a historical source and prevents prestige narratives from outrunning the evidence.

39.29 What Tirhuta can and cannot prove about social identity

A Tirhuta manuscript can demonstrate that a scribe or copying milieu knew the script. It can sometimes connect a text to a place, patron, teacher or archive. It cannot, by itself, prove the caste of every reader, the mother tongue of the scribe, the original language of an exemplar or the age of the underlying composition. Modern claims that the script inherently belongs to one social group are especially risky because the surviving archive is selective and because print-era politics changed the social distribution of literacy. Script is evidence of practice, not an automatic identity certificate.

39.30 Conclusion: scribal culture as a history of transmission

Tirhuta/Mithilakshar is best understood not as a relic but as a long history of transmission. Its palaeographic ancestry links Mithila to the broader eastern Indian script world; its medieval differentiation supported regional scholarly and literary copying; its manuscripts carried Sanskrit and Maithili across households, courts, schools and Nepalese repositories; its decline in routine print use widened the gap between modern readers and older archives; and digital encoding has created new possibilities of access and revival. The central historical lesson is that script, language, text and community move at different speeds. A source-critical history preserves those differences while showing how scribes repeatedly connected them.

Table 39.1 — Evidence domains for Tirhuta/Mithilakshar and scribal history

Evidence domain	What it can establish	What it cannot establish alone	Preferred control
Palaeography	Relative development of letterforms and scribal hands	A precise date or fixed script-name for every earlier ancestor	Compare dated witnesses and related eastern scripts
Material / codicology	Support, folio structure, repairs, binding and use history	Date of original composition	Combine with colophon, palaeography and provenance
Colophon	Often the copy date, scribe, patron, place or ownership	Automatic date of the work itself	Check whether colophon is original, copied or later
Language + script	Which language is written in which graphic system in a witness	One-to-one identity between language and script	Record language and script separately
Anthology / attribution	How a manuscript compiler or scribe labels a text	Certain original authorship	Compare hands, sequence, parallel witnesses and external evidence
Regional provenance	Where a witness was copied, owned or preserved when documented	Where the text was first composed	Separate preservation geography from composition geography
Print conversion	Changing readership, type economy and modern standardisation	Disappearance of manuscript use at the same moment	Track manuscript-print coexistence
Unicode / digital text	Interoperable character encoding and searchable transcription	Facsimile of every historical glyph or page feature	Link encoded transcription to manuscript images

Chapter 40 — Oral Culture

Oral culture is not the unwritten residue left after “literature” has been removed. It is a social system of memory, performance, argument, pleasure and transmission in which words are inseparable from voice, occasion, audience, gesture and place. In Mithila, Vajji and Anga, songs, tales, proverbs, ritual speech, narrative chants, joking, lament, praise and epic performance have carried historical experience across households and communities that were only unevenly represented in manuscripts and formal chronicles. Yet oral evidence requires chronological discipline. A song recorded in the nineteenth or twentieth century may contain older language or motifs, but its present form cannot simply be projected into the medieval period. This chapter therefore reconstructs oral culture through a hierarchy of dated witnesses, ethnography and performance analysis, while treating continuity as a question to be demonstrated rather than assumed.

40.1 Oral culture as a historical archive

Oral culture preserves information differently from a charter, inscription or manuscript. Its archive exists in people, repertoires and repeated social occasions. A tale survives because someone knows when to tell it; a marriage song survives because a sequence of ritual acts calls it forth; a ballad survives because performers and audiences continue to value the hero, melody or social claim embodied in it. The result is both durable and flexible. Themes may remain stable while wording changes; episodes may migrate between genres; a performance may answer a new political situation with old narrative material. For social history this mobility is an advantage, because it gives access to values and conflicts often absent from official records. It is also a warning: oral memory is not a sound recording of the past. The historian must ask which layer of a performance is actually dated and which is an inference.

40.2 Evidence hierarchy: performance, recording and earlier reference

This volume distinguishes at least four evidentiary layers. The first is the living or recently observed performance itself. The second is a dated recording, transcription, ethnography or printed collection. The third is an earlier reference that names a genre, performer, tale, shrine or song. The fourth is historical inference about origins or continuity. These layers do not carry equal chronological force. George A. Grierson’s nineteenth-century transcription of Raja Salhesh is firm evidence that the narrative was circulating then; it is not, by itself, a dated medieval manuscript of the same wording. Coralynn V. Davis’s ethnography of Maithil women’s tales gives exceptionally rich evidence for late-twentieth- and early-twenty-first-century storytelling practice, but the antiquity of individual motifs must be established independently. A responsible oral history keeps these layers visible.

40.3 Orality and literacy were not opposing worlds

Premodern societies were rarely either “oral” or “literate.” A Sanskrit or Maithili manuscript could be read aloud, memorised, paraphrased and retold; a song learned by ear could later be copied into an anthology; a performer might know both written and unwritten versions. Chapter 39 showed that manuscripts were social objects used in teaching, ritual and performance. Oral culture occupied the same ecology. Recitation allowed written knowledge to reach people who did not read the script, while scribal copying could stabilise material that had previously circulated more fluidly. The two media therefore interacted continuously. The useful historical question is not whether a community possessed writing but which activities required writing, which depended upon memory and performance, and where the two met.

40.4 The performance event is part of the text

A transcript captures words but usually reduces the event that gave those words meaning. Who sang first? Who was allowed to answer? Was the performance public, domestic, ritual, competitive or comic? Did listeners interrupt, correct or request an episode? Were instruments, dance, gesture, costume or offerings involved? Such features can alter meaning without changing a line of text. Ruth Finnegan’s work on oral poetry emphasises that performance is constitutive rather than decorative, and the same principle is vital in Mithila–Vajji–Anga. A departure song at a wedding, a shrine narrative, a joking exchange at a women’s gathering and a staged Salhesh performance may all be “oral texts,” but they occupy different social spaces and create different kinds of authority.

ORAL TRADITION AS A CHAIN OF EVENTS

Historical claim must match the dated stage of evidence

A modern performance may preserve older material, but it does not by itself date every word, motif or social category.

Figure 156 — Oral tradition as a chain of evidentiary events

40.5 Women’s storytelling and domestic counter-archives

Women’s oral traditions are especially important because domestic life is thinly documented in formal political sources. Coralynn V. Davis’s study on the Nepal–India border shows Maithil women using folktales to think through fortune, marriage, kinship, suffering, virtue, household hierarchy and female solidarity. The tales are not simple mirrors of society. They reorganise experience through fantasy, irony and moral reversal, sometimes giving speech or agency to characters who lack power in everyday arrangements. This makes women’s storytelling a counter-archive of social relations. It should not be romanticised as automatically resistant, since tales may also reproduce hierarchy and normative expectations. Their historical value lies in the range of positions they make narratable.

40.6 Birth songs, blessing and the social arrival of a child

Birth repertoires such as sohar-type songs turn a biological event into a recognised social arrival. They may bless mother and child, invoke divine or epic precedents, joke about relatives, express hopes for prosperity, and place the newborn within gendered and kinship expectations. The form is widely distributed across north India, so similarity alone cannot establish a uniquely Maithili origin. What matters for regional history is the local language, named kin relations, melodic practice, household setting and ritual sequence in which a particular song is performed. Collections such as Makhan Jha’s survey of Mithila folklore preserve

examples of birth and other ceremonial songs, but their publication date must not be confused with the date of composition of every item.

40.7 Marriage songs as a social commentary on alliance

Marriage concentrates many of the themes explored in Chapters 31 and 32: lineage, alliance, property, distance, gender and household transfer. Oral performance makes those structures audible. Wedding songs can praise bride and groom while simultaneously mocking affines, lamenting separation, criticising the groom's party or dramatising the vulnerability of a daughter leaving her natal home. Because the songs belong to particular ritual moments, the same wedding may contain mutually contradictory voices—auspicious blessing beside sharp satire, obedience beside complaint. This polyphony is historically valuable. It shows that normative marriage ideology did not exhaust the emotional and argumentative life of marriage. But present-day song texts cannot simply be used as literal evidence for medieval marriage rules without earlier corroboration.

40.8 Departure, samdaun and the geography of emotion

Departure songs often convert geography into emotion. The bride's movement from natal to marital household is imagined through roads, rivers, vehicles, thresholds and distances; relatives are remembered by the spaces they occupy. In Mithila, the broad category often described as samdaun is associated with farewell and separation, but local terminology and repertoire vary. Such songs can help historians understand the social meaning of patrilocal marriage and the affective importance of the natal home. They can also register transformations in transport and migration when new objects or destinations enter the verse. A song therefore has more than one historical layer: an older structure of feeling may absorb newer vocabulary and circumstances.

40.9 Agricultural seasonality and work rhythms

Oral culture was tied to the agricultural calendar as much as to life-cycle ritual. Sowing, transplanting, harvesting, cattle care, monsoon waiting and seasonal leisure created different opportunities for collective singing and narrative. Work songs can coordinate bodily rhythm, relieve monotony, encode practical knowledge or turn labour relations into humour and complaint. Their survival is uneven because mechanisation, migration and changing labour organisation alter the contexts that once sustained them. For the historian, disappearance is itself evidence: a genre may contract not because people have forgotten "tradition" in the abstract but because the social occasion that produced repeated performance has changed.

Figure 157 — The performance ecology

40.10 Festivals and ritual repertoires

Festival traditions such as Sama-Chakeva, Madhushravani and other seasonal observances of the Mithila region combine objects, movement, song, narrative and gendered participation. Their contemporary forms are important evidence for how community is enacted through repeated performance. They also illustrate why folklore should not be reduced to text. Clay figures, baskets, courtyards, ponds, processions and food may be as necessary to the event as the words sung. Historical reconstruction must separate the documented age of a festival name or ritual prescription from the age of particular songs now attached to it. Later standardisation, school programmes, tourism and state-sponsored festivals can also reshape repertoire.

40.11 Tale cycles, wit and the Gonu Jha problem

Gonu Jha tales are among the best-known humorous narratives associated with Mithila. The protagonist defeats greed, pedantry or authority through wit, trickery and verbal reversal. Yet the popularity of a named tale-cycle creates a dating trap. A modern collection may gather stories that had circulated anonymously, under different trickster names, or in neighbouring languages. The historical Gonu Jha, if recoverable, is therefore not automatically the author or origin of every tale attributed to him. The more defensible approach treats “Gonu Jha” as a powerful regional narrative magnet: a name under which comic social intelligence has been collected, localised and continually renewed.

40.12 Raja Salhesh and the politics of remembered dignity

The Raja Salhesh tradition is a major example of oral culture carrying community history and dignity. Grierson printed a version in the nineteenth century, and later documentation records Salhesh in song, theatre, painting and shrine practice among Dusadh communities in Bihar and Nepal. The tradition remembers a hero who overcomes rivals and commands supernatural as well as political power. Modern interpreters have rightly highlighted its significance for Dalit cultural assertion. Historical care is still necessary: the nineteenth-century transcription is an early documented witness, not proof that every present episode existed in precisely that form centuries earlier. What can be shown securely is a long, socially embedded tradition whose meanings have continued to change.

40.13 Lorik: pastoral epic across regional boundaries

The Lorik cycle demonstrates that oral epics ignore modern linguistic borders. Grierson's study of the "Birth of Lorik" described a long heroic legend widely sung among Ahir/Yadav pastoral communities in Bihar and adjoining parts of north India. Versions circulate across Bhojpuri, eastern Hindi and Bihari-language zones, and the hero's geography shifts with performers. For this volume the point is not to claim Lorik as the exclusive possession of Mithila, Vajji or Anga, but to recognise the region as part of a wider pastoral performance network. Cattle, mobility, martial honour, romance and clan memory give the epic its social force. Variation between versions is evidence of circulation, not corruption of a single lost original.

40.14 Sita, Janak and the localisation of epic memory

Mithila's identification with Sita and Janak allows Ramayana narratives to be localised with unusual intensity. Weddings, women's songs, pilgrimage speech, temple narratives and place legends can bring Sita into domestic and regional space rather than leaving her only in a Sanskrit or written epic. Oral retelling may emphasise daughterhood, marriage, separation, maternal grief or relations between affinal households in ways different from elite textual priorities. Such versions should be read as interpretive traditions, not as defective copies of a canonical Ramayana. At the same time, the presence of an epic motif in a modern song does not prove that the song itself is ancient; canonical stories are continuously re-vernacularised.

40.15 Puranic and devotional narrative in everyday speech

Rama, Krishna, Shiva, local goddesses, saints and sacred places enter oral culture through stories that circulate far beyond formal recitation. A household explanation of a fast, a shrine origin story, a child's tale and a festival song may all rework Puranic narrative. This process connects Sanskritic, vernacular and local religious worlds without requiring a simple model of "high" culture descending into "folk" culture. Local performers select, reinterpret and sometimes contradict textual precedents. The history of religion therefore includes not only which scriptures were copied but how narratives were remembered, shortened, moralised and attached to particular ponds, trees, shrines and villages.

40.16 Ballad, epic, chant, tale and proverb are different genres

The label "folklore" can conceal important formal differences. A long heroic gatha depends on episodic memory and performance stamina; a proverb works by compression; a folktale depends on plot and teller-audience interaction; a ritual chant may be effective because its formula is repeated correctly; a wedding song may be inseparable from a specific act. Historical interpretation should therefore begin with genre. The same motif can mean different things in different forms. A king in a comic tale is not evidence of kingship in the same sense as a king named in a praise ballad, and neither is equivalent to an inscription. Genre is not merely literary classification; it determines how memory is stored and what kinds of truth a community expects from the performance.

40.17 Performers, specialists and unequal cultural labour

Oral repertoires are sustained by people whose labour is often poorly represented in written archives: singers, drummers, dancers, ritual specialists, genealogists, mendicants, storytellers and performers attached to particular communities. Some performances are open and collective; others require specialist training or hereditary knowledge. Patronage may come from households, landlords, shrines, fairs, caste associations or modern cultural institutions. This social organisation matters because it shapes what survives. A repertoire

without patrons or apprentices may disappear even when older people remember it. Conversely, a tradition can expand when a community invests in public performance as a marker of identity or dignity.

40.18 Music, rhythm, gesture and embodied memory

Words are only one storage system in oral tradition. Melody cues the next line; drum patterns organise entrances; gesture marks character and emotion; dance sequences carry narrative; repeated bodily action fixes ritual order. These forms of embodied memory can preserve structure even when verbal wording changes. They also make transcription inadequate as a complete record. A nineteenth-century collector who wrote down the “text” of a song may have captured something valuable while losing tempo, tune, audience response and performance space. Modern audio-visual documentation can recover more of the event, but it too frames the performance through microphone, camera, editing and the knowledge that recording is taking place.

40.19 Fairs, shrines and markets as transmission nodes

Households are not the only centres of oral circulation. Weekly markets, seasonal fairs, pilgrimage centres and shrines assemble people who normally live apart. Performers can encounter new audiences, learn episodes from other singers, sell printed booklets or recordings, and attach regional heroes to new locations. Salhesh shrines illustrate how narrative, ritual and material representation reinforce one another. Such sites help explain why oral traditions can spread over large areas without central institutions. They also complicate the idea of a pure village tradition: mobility, exchange and performance competition have long been part of rural cultural life.

40.20 Marriage migration as a route of cultural transfer

Patrilocal marriage moves not only women but repertoires. A bride may carry songs, tales, ritual knowledge, pronunciation and foodways from her natal village into a new household, while later visits renew connections in both directions. Across generations this process creates overlapping oral maps that do not correspond neatly to administrative districts. It also helps explain why neighbouring varieties of Maithili, Bajjika, Angika, Bhojpuri and Nepali can share motifs while retaining local forms. Because women’s mobility was structured by marriage, some cultural transmission that looks “anonymous” in the archive was in fact carried through highly specific kinship routes.

ROUTES OF ORAL CIRCULATION

Household & courtyard	life-cycle songs, tales, ritual speech
Village & neighbourhood	work, worship, recreation, specialist performance
Fair, shrine & market	mobile audiences, ballads, devotional repertoires
Marriage migration	songs and tales cross household and locality
India–Nepal corridor	Janakpur–Terai–north Bihar circulation
Print, radio & digital media	new reach; new fixing and remixing of performance

Figure 158 — Routes of oral circulation

40.21 The India–Nepal Mithila corridor

Janakpur, the Nepal Terai and north Bihar form a particularly important field for oral circulation. Political boundaries did not eliminate marriage, pilgrimage, trade or linguistic contact across the frontier. Ram Dayal Rakesh’s work on Nepalese folk culture and Coralynn Davis’s ethnography both show Maithil cultural practice spanning the India–Nepal border. The historian should therefore avoid treating Nepalese Maithil material as external evidence or Indian material as automatically representative of Nepal. Cross-border comparison is most useful when locality, date and performer are retained rather than dissolved into an undifferentiated “Mithila tradition.”

40.22 Vajji and western Mithila: corridors rather than hard borders

The western part of the larger Mithila–Vajji zone has long interacted with the middle Ganga plain. Oral speech forms and repertoires grade across territory rather than stopping at a linguistic line. Later labels such as Bajjika are analytically useful for modern language history, but Chapter 36’s warning against backward projection applies here: a present-day language name should not be assumed to define the social boundaries of every earlier performance. For oral history the better unit may be the route—market, river crossing, pilgrimage path, marriage network or seasonal labour circuit—through which singers and stories moved.

40.23 Anga and the eastern zone

Anga and the Bhagalpur–Munger region connect the study area toward Bengal, the Santhal Parganas and the middle Ganga. Angika-speaking communities possess their own song, proverb and narrative repertoires, while broader Bihari and eastern Indian traditions cross the same space. A history centred only on Darbhanga or north-central Mithila would therefore miss eastern circulation. Yet evidence remains uneven: many local repertoires are better documented in twentieth-century folklore collections than in earlier archives. The correct response is not to invent an unbroken ancient genealogy but to record the documented layers and identify where earlier evidence is still needed.

40.24 Multilingual performance and code-switching

Performers may shift language or register according to character, audience, refrain, prestige or melody. A devotional line can preserve Sanskrit vocabulary; a comic passage may intensify local speech; a market performer may accommodate listeners from a neighbouring language zone. Oral multilingualism thus differs from modern standard-language ideology. It also cautions against assigning a performance to a single “language” solely from an edited printed text. Collectors often normalise spelling or translate unfamiliar words, masking the code-switching of the event. For the history of Maithili, Angika and Bajjika, recordings and careful field transcription are especially valuable because they preserve variation that print may smooth away.

40.25 Oral transmission and literary Maithili

Literary Maithili did not develop outside oral performance. Songs, drama, recitation and memorised verse connected written composition to listeners. The Padavali tradition associated in this volume with the earlier Mahakavi Vidyapati is a particularly important case: lyric survives through performance as well as manuscripts, and later singers could reshape pronunciation, sequence and attribution. Oral circulation therefore helps explain literary longevity, but it cannot by itself solve authorship or chronology. The two-Vidyapati distinction adopted in Chapter 38 must continue to rest on a combined assessment of textual, manuscript, linguistic and historical evidence rather than on the prestige of a name in later song tradition.

40.26 Collectors and the making of “folklore”

Colonial and early modern collectors preserved material that might otherwise be lost, but collection itself transforms oral culture. A collector chooses whom to ask, which performance to stop and write down, how to spell dialect forms, whether to translate, and what to classify as a “song,” “legend” or “superstition.” Grierson’s Maithili chrestomathy is invaluable precisely because it records language and oral material at a dated historical moment. It also reflects nineteenth-century categories and social descriptions that require critical reading. Later folklorists likewise selected and edited. The printed archive must therefore be studied as a history of documentation as well as a repository of performances.

40.27 Print, radio, cassette and digital remediation

Once oral material enters print or electronic media, it does not cease to be oral. Instead, performance acquires new feedback loops. Printed songbooks can standardise lyrics that singers later memorise; radio creates regional stars; cassette culture accelerates circulation; video platforms make local performances globally searchable and encourage shortened or visually spectacular forms. A “traditional” performance today may therefore contain layers learned from recordings rather than solely from face-to-face transmission. This remediation should be documented, not treated as contamination. Media history is now part of oral history because it changes who can perform, who can listen and which version becomes widely recognised.

40.28 Gender, caste and the politics of audibility

Oral culture can make marginalised experience audible, but archives do not preserve all voices equally. Women’s domestic stories may be inaccessible to male collectors; low-status performers may be described without being named; elite patrons may receive credit for performances produced by others. The Salhesh tradition shows how a community can use folklore to articulate dignity and historical presence, while Davis’s work demonstrates how women’s storytelling engages household power. These examples warn against a single “folk voice.” Oral culture is internally stratified. The historian must ask who had the right to perform

publicly, who controlled ritual spaces, who was recorded, whose language editors corrected, and whose versions later became canonical.

40.29 A source-critical workflow for oral traditions

This volume uses a reproducible workflow. First identify the performance or recorded witness: performer, place, date, language, occasion and collector. Second describe the genre and performance conditions before extracting historical claims. Third compare multiple versions to separate stable structures from local or recent additions. Fourth search for earlier dated references in manuscripts, print, administrative records, ethnography, shrine evidence or inscriptions. Fifth distinguish the date of documentation from the proposed date of origin. Sixth preserve disagreements rather than harmonising every variant. Finally, where continuity cannot be demonstrated, say so. This method makes oral evidence stronger, not weaker, because it prevents historical value from depending on claims of impossible verbatim antiquity.

EVIDENCE FIREWALL FOR ORAL HISTORY

Figure 159 — Evidence firewall for oral history

40.30 Conclusion: a history carried by voices

The oral cultures of Mithila, Vajji and Anga reveal social worlds that political chronology alone cannot recover. They preserve household argument, women's experience, pastoral heroism, community dignity, ritual obligation, humour, devotion, migration and regional memory. Their forms travel through marriage, markets, fairs, shrines, manuscripts, print and digital media; in every movement they may change. Historical method must therefore hold two truths together: oral traditions can preserve deep cultural structures, and every actual performance belongs to a specific present. By dating witnesses carefully and treating variation as evidence, oral culture becomes neither timeless folklore nor unreliable anecdote, but a disciplined archive of social history.

Table 40.1 — Evidence domains for oral-culture history

Evidence domain	What it can establish	Principal limit
Observed or recorded performance	Who performed what, where, when, for whom, and under which social conditions	Does not by itself establish the antiquity of every word, motif or institution

Evidence domain	What it can establish	Principal limit
Dated transcription or folklore collection	A terminus by which a version or genre was documented	Collector selection, normalisation and loss of sound, gesture or context
Earlier textual or archival reference	Earlier existence of a name, genre, performer, shrine or motif	Reference may not describe the same version known today
Material and ritual setting	Shrines, objects, instruments, performance spaces and recurrent occasions	Material continuity does not guarantee unchanged narrative content
Variant comparison	Stable structures, mobile episodes, local additions and transmission routes	Shared motifs can arise through borrowing; similarity is not a date
Ethnography and oral history interview	Social meanings, performer biographies, memory of change and transmission	Retrospective memory is situated and must be cross-checked

Chapter 41 — Angika and the Eastern Linguistic-Cultural Zone

Angika belongs to the eastern edge of the historical field studied in this volume, but the word itself cannot be allowed to do the work of history. Ancient Anga, medieval eastern vernaculars, colonial descriptions of Chhika-Chhiki, and the modern literary-linguistic identity called Angika are related objects of inquiry, not automatically identical ones. This chapter therefore studies an eastern linguistic-cultural zone centred on the Bhagalpur–Champa and Munger corridors and extending through graded contact toward Purnia, the Santal Parganas, Bengal and the wider Ganga valley. Its method is deliberately double: it takes present Angika identity seriously while refusing to project present labels unchanged into periods for which the evidence uses other names.

41.1 Why an eastern linguistic-cultural zone is a better starting point

Language maps are useful summaries, but they easily turn gradual transitions into hard borders. The eastern part of the Mithila–Anga field has never been organised by speech alone. Rivers, ferries, market towns, pilgrimage routes, marriage networks, military corridors, seasonal labour and administrative centres connected communities whose repertoires overlapped without being identical. The term “zone” therefore does not deny linguistic difference; it asks how difference was produced and maintained inside a field of repeated contact. Bhagalpur, Munger, the Kosi–Purnia corridor and the Santal Parganas occupy different positions in that field. A history of Angika must explain both internal coherence and permeability. It should be able to describe why speakers recognise a distinctive regional speech while also showing why its features intersect with Maithili, Magahi, Bengali, Santali and other neighbouring languages. This approach also prevents the modern political boundary of a district or state from becoming an imaginary medieval linguistic frontier.

41.2 Ancient Anga and modern Angika: the naming problem

The resemblance between the ancient regional name Anga and the modern name Angika is historically important, but resemblance is not proof of uninterrupted linguistic identity. Ancient texts can establish the existence, reputation and political geography of Anga; archaeology can recover settlements, trade and material culture; neither source automatically tells us the structure of the everyday speech spoken there centuries later. New Indo-Aryan languages emerged through long transformations from Middle Indo-Aryan and regional vernacular fields, not through the simple survival of a mahajanapada label. The responsible question is therefore not “Was the language of ancient Anga already Angika?” but “What chains of evidence connect later eastern speech forms to earlier populations, routes and cultural regions?” The distinction matters because regional pride is strengthened, not weakened, when continuity is demonstrated through dated evidence rather than asserted from a name alone. This chapter consequently treats ancient Anga as historical context and modern Angika as a later linguistic identity whose earlier genealogy must be reconstructed stage by stage.

41.3 Eastern Indo-Aryan as a continuum of related innovations

Angika is part of the eastern Indo-Aryan world in which related languages share inherited structures as well as features produced through contact. Genealogical relationship does not require identical classification by every scholar. The speech varieties of Bihar and adjoining eastern India developed within overlapping historical networks, and several boundaries are better understood as bundles of features than as single lines.

Pronouns, case markers, verb agreement, honorific distinctions, vowel qualities and lexical choices may each have their own geography. A speaker can therefore sound recognisably eastern-Bihari while using a feature shared with Maithili in one domain and with Magahi or Bengali in another. This is normal linguistic history, not evidence of corruption or impurity. The older philological habit of ranking varieties by “purity” is especially misleading in a trade and migration zone. The historical task is to identify which features are inherited, which are areal, which are borrowed, and which became emblematic only after modern literary standardisation.

41.4 The Ganges: boundary, highway and linguistic hinge

Colonial descriptions often used the Ganges as a convenient linguistic divider, particularly when contrasting north-bank Maithili with speech to the south. Yet the same river was a transport highway that connected rather than merely separated communities. Bhagalpur’s position on the Ganges made it a node where boat traffic, pilgrimage, grain, textiles, officials, soldiers and migrants could circulate. Linguistic boundaries near such a river are therefore likely to be asymmetric: some features may align strongly with a bank, while vocabulary and performance traditions cross by ferry, trade and marriage. The old Munger district evidence is revealing precisely because it records Chhika-Chhiki in a south-Gangetic tract while also describing Magahi farther west and Santali in adjoining areas. The river should thus be treated as a hinge. It can reinforce a regional contrast through settlement history and administrative geography while simultaneously enabling the social contacts through which speech repertoires change.

Angika and the eastern linguistic-cultural zone

Analytical point: the zone is a network of graded transitions, not a language line on a map.

Figure 160 — Angika and the eastern linguistic-cultural zone

41.5 Grierson’s Chhika-Chhiki: a dated description, not a timeless essence

The Linguistic Survey of India is indispensable because it records speech under identifiable late-nineteenth- and early-twentieth-century conditions. Grierson used the label Chhika-Chhiki for a variety associated with the Bhagalpur–Munger side of the Maithili field and printed specimens and grammatical observations. The label is valuable evidence for what he heard, collected and classified; it is not a medieval autonym and should not be projected backward. Nor should every modern Angika variety be reduced to one survey specimen. Survey categories reflect sampling, the questions asked, the informants selected and the classificatory architecture of their time. Even so, Grierson’s record establishes an important historical

baseline: the eastern/southern variety was recognised as distinct enough to describe separately while being placed by him within Maithili. Modern discussions of Angika cannot responsibly ignore this baseline, but neither are they compelled to reproduce Grierson's hierarchy unchanged.

41.6 What “southern Maithili” meant in the survey tradition

When an older survey calls Chhika-Chhiki a southern variety of Maithili, the phrase must be read as a classificatory judgement made within a broader Bihari survey, not as a statement that later linguistic identities did not or could not emerge. Grierson distinguished Standard, Western, Eastern and other Maithili varieties, and his arrangement was simultaneously geographic and structural. The term “southern” also covered a contact-rich environment unlike the Darbhanga-centred literary norm that later became especially visible in print. A dialect label can therefore encode two facts at once: linguistic relationship and sociolinguistic inequality. Varieties may be closely related yet differ sharply in literary institutions, prestige, orthographic practice and self-identification. For this volume, Grierson's classification is historical evidence of one scholarly model. It is neither suppressed to favour modern separatism nor treated as an eternal verdict that invalidates later Angika literary and political self-definition.

41.7 The modern name Angika and the making of a literary identity

During the twentieth century, Angika became increasingly prominent as a name used in regional literary production, grammar writing, dictionaries, periodicals, cultural organisations and campaigns for recognition. This transformation matters historically because standard languages are not discovered fully formed; they are built through repeated acts of naming, codifying, teaching and publishing. Regional scholars produced histories of Angika literature, grammatical descriptions and collections of folklore, thereby creating an archive in which speakers could recognise a shared written tradition beyond local village speech. Such institution-building does not make the language “artificial.” It demonstrates how a speech community converts everyday linguistic practice into a consciously named public language. At the same time, the modern success of the name should not be used to rename every earlier eastern text without philological demonstration. The emergence of Angika as a literary identity is itself a major historical development and should be dated rather than projected backward.

41.8 Classification today: two legitimate descriptive frames coexist

Contemporary reference works illustrate why this history should not be forced into a single classificatory slogan. A 2025 Central Institute of Indian Languages publication, while describing Maithili varieties, maps modern Angika to Grierson's Chhika-Chhiki and treats it within a Maithili varietal framework. Glottolog, by contrast, catalogues Angika as a separate spoken language with ISO 639-3 code *anp*. These are not interchangeable institutional decisions. One foregrounds continuity within a Maithili dialect complex; the other provides a distinct language entry for cross-linguistic cataloguing. Neither classification by itself settles social identity, literary history or the exact location of every speech boundary. The productive historical question is how and why different frameworks became plausible. This chapter therefore records both. Where a source says Chhika-Chhiki or southern Maithili, that wording is retained; where modern speakers and institutions say Angika, that identity is likewise retained.

Classification is historical: labels change with institutions

No single classificatory label should be projected backward as if it were timeless.

Figure 161 — Classification is historical: labels change with institutions

41.9 Phonology as regional evidence, not a badge of purity

Descriptions of Angika often emphasise characteristic vowel qualities and word-final vocalic effects, including features already noticed in colonial accounts of Chhika-Chhiki. Such observations are useful when supported by recorded speech, but they should be analysed as distributions rather than slogans. A sound feature can have a strong core area and still fade gradually toward neighbouring speech. It may vary by age, settlement, caste, gender, education, mobility or style. Modern orthographic proposals that introduce special signs for locally salient vowels reveal something else: once a speech variety enters deliberate standardisation, writers must decide which phonetic distinctions deserve graphic representation. Those decisions can sharpen a contrast that everyday bilingual speakers manage more fluidly. For historical reconstruction, phonology is strongest when multiple dated recordings or transcriptions can be compared. A single eye-catching pronunciation cannot establish the boundaries or antiquity of an entire language.

41.10 Grammar: shared structures and locally weighted choices

Angika grammar participates in a broader eastern Indo-Aryan typological field while displaying locally favoured forms. Pronoun systems, genitive constructions, copular and auxiliary patterns, honorificity and verb morphology are especially useful for comparison because they are less easily borrowed wholesale than isolated vocabulary. Yet even grammar changes through contact and levelling. The correct unit of analysis is therefore a bundle of constructions across speakers and places, not a short list of emblematic words. Modern descriptive materials show that Angika writers are actively codifying grammar for schooling and print; such codification provides valuable contemporary evidence but should not be mistaken for a direct photograph of medieval usage. A historical grammar of the eastern zone would ideally compare Grierson's specimens, later regional grammars and present-day corpora, marking which forms persist, which have receded and which have been promoted as standard.

41.11 Lexicon as an archive of contact

Vocabulary is often the most visible record of cultural contact. The eastern zone has interacted with Sanskritic learning, Persianate administration, Urdu and Hindi public spheres, Bengali commerce and print,

Santali and other Munda-speaking communities, and the technical vocabularies of modern schooling and migration. Borrowing does not imply language replacement. Loanwords may cluster in administration, religion, craft, market exchange or urban life while basic household vocabulary remains comparatively stable. Words also travel through songs and marriage rather than through formal institutions. For Angika history, lexical layers should be dated whenever possible by texts, glossaries, recordings or occupational archives. Apparent similarity with a neighbouring language may represent common inheritance, parallel innovation or borrowing; each possibility requires testing. The eastern zone is especially valuable because it allows historians to connect vocabulary with concrete routes of interaction instead of treating words as detached evidence.

41.12 Bhagalpur–Champa as a riverine linguistic node

Bhagalpur and the older Champa landscape sit at the centre of the eastern zone's historical imagination. Their importance is not that an ancient city can be assigned a modern language by fiat, but that long-lived settlement, trade and religious activity created repeated opportunities for multilingual interaction. Urban and peri-urban centres draw people from villages, market networks, river traffic and administrative jurisdictions. They also generate new registers: bargaining, clerical prose, religious performance, schooling and later journalism. A speech variety associated with Bhagalpur can therefore develop urban recognisability without erasing internal rural diversity. The Bihula–Bishahari narrative and Manjusha painting further show how a regional story can link language, ritual, craft and place. The linguistic history of Bhagalpur is consequently best written beside its economic and cultural history, not as a detached list of grammatical traits.

41.13 Munger and Kharagpur: a transition belt in the records

Historical descriptions of the Munger region are particularly instructive because they refuse the simplicity of a single-language district. The eastern portion and Kharagpur country were described with Chhika-Chhiki forms closely resembling Bhagalpur speech, while Magahi was reported farther west; Santali also appeared in parts of the wider district. Such records demonstrate why administrative borders cannot be equated with linguistic borders. Munger was a transition belt in which different speech systems were geographically patterned but socially adjacent. This pattern also offers a caution for modern maps: when a contemporary label is extended over an entire district, it may hide older local contrasts. The historical method should therefore work below district scale whenever sources permit, using thana, village, route and market-level evidence. Transitional areas are not peripheral noise. They are often where the mechanisms of linguistic change become most visible.

41.14 Kosi–Purnia and the north-eastern transitions

North-eastward, the linguistic landscape becomes even more layered. Kosi movement, floodplain resettlement, market migration and routes toward Purnia, north Bengal and the Nepal Terai complicate any simple extension of a Bhagalpur-centred norm. Modern labels such as Angika, Surjapuri, Maithili, Bengali and Hindi organise this space differently depending on the institution and the speaker. Historical sources likewise shift in terminology. Rather than forcing the whole corridor into one category, this volume treats it as a transition zone whose speech communities have long negotiated multiple centres of prestige. The same household may interact with one language in ritual, another in school, another in administration and a local variety in everyday life. Such functional multilingualism is historically normal. Mapping it requires attention to movement, not only birthplace.

41.15 Santal Parganas and Munda-language contact

The south-eastern edge of the Angika field meets one of eastern India's major Munda-language regions. This contact must be approached without assuming that every shared word is borrowed or that one community passively receives another's speech. Markets, agricultural labour, forest products, tenancy, mission education, administration and migration created recurrent bilingual encounters. Dipankar Dasgupta's study of Ghatoali and Mal-Paharia, and later classifications that recognise an Angika connection in the region, remind us that small local varieties may preserve especially complex histories of contact. Such settings can produce lexical transfer, phonological accommodation and code-switching while maintaining distinct ethnic identities. For social history, the key point is that Angika's eastern zone was never exclusively Indo-Aryan in its cultural ecology. Munda-speaking communities were participants in the making of regional markets, performance worlds and everyday multilingualism.

41.16 Contact with Bengali: adjacency without automatic derivation

The eastern reach of the zone opens toward Bengal, and some Angika features have often been compared with Bengali pronunciation or vocabulary. Geographic adjacency makes contact unsurprising, especially through Bhagalpur's trade, rail and river connections and through movement toward Malda and other Bengal-facing districts. Yet similarity must not be converted into a simplistic origin story. Angika and Bengali are related Indo-Aryan languages with both inherited commonalities and later areal convergence. A feature shared by them may be old, borrowed, or independently developed. Historical proof requires chronology. Bengali print culture and education also influenced eastern Bihar in the nineteenth and twentieth centuries, creating new lexical and literary contacts that are much easier to document than medieval phonological borrowing. The safest account distinguishes genetic relationship from contact-induced convergence and assigns dates only where the evidence permits.

41.17 Contact with Magahi: the western and south-western gradient

Toward the west and south-west, Angika speech meets Magahi varieties across a broad gradient rather than a wall. The older Munger descriptions already show this adjacency. Shared agrarian vocabulary, similar sociolinguistic pressures and mobility through the middle Ganga plain create conditions for convergence. At the same time, speakers may use particular grammatical or phonological forms to index local identity precisely because neighbouring speech is so intelligible. Such boundary marking is a social process: difference becomes salient where interaction is frequent. A historical comparison of Angika and Magahi should therefore combine structural linguistics with settlement and mobility history. It should also resist a common error in nationalist language histories—the assumption that mutual intelligibility proves dialect status or, conversely, that strong identity proves remote genetic distance. These are different questions.

41.18 The Maithili linkage: genealogy, literary prestige and contested identity

The Angika–Maithili relationship is central because it is simultaneously linguistic, historical and political. Grierson's survey placed Chhika-Chhiki inside Maithili; modern CIIL work can still employ a comparable varietal mapping. Angika literary institutions, however, have developed a strong separate name and public identity. These facts can coexist. Genealogical closeness does not dictate how communities must organise literature, education or cultural recognition, just as political self-identification does not erase structural comparison. The historical task is to document when particular labels became dominant, what varieties they covered, and which institutions promoted them. This volume therefore avoids both polemical shortcuts: it does not call modern Angika merely “misnamed Maithili,” and it does not rewrite every older Chhika-Chhiki

or southern-Maithili description as if scholars had always recognised a separate Angika language. The tension itself belongs to history.

41.19 Persian, Urdu and Hindi layers in the public sphere

The eastern zone's linguistic ecology also includes supraregional administrative and literary languages. Persian shaped official and elite documentary culture in earlier periods; Urdu and Hindi became important in urban, educational and print domains under later regimes. These languages supplied vocabulary but also registers of politeness, bureaucracy, law, poetry and public debate. The effects were uneven: a village song, a court petition and a railway-station conversation could display different proportions of borrowed vocabulary. Modern Hindi schooling created another layer by encouraging speakers to move between local speech and a standard language with wider institutional reach. Such diglossic or multilingual competence should not be interpreted as the disappearance of Angika. It shows how local identity can persist inside a hierarchy of domains. For historians, the changing public languages of Bhagalpur and Munger are essential to understanding why local speech was sometimes under-recorded even when widely used.

41.20 Scripts: Kaithi, Devanagari and the problem of “Anga Lipi”

Modern Angika is commonly written in Devanagari, while regional writing historically also interacted with Kaithi and other eastern scripts. Claims for a continuous ancient “Anga Lipi” require much greater caution. The Lalitavistara's famous list of script names can show that a tradition remembered a script associated with Anga; it does not by itself prove that a specific surviving signary was the direct ancestor of a modern Angika writing system, still less that the same script remained continuously in use for two millennia. Script history requires dated inscriptions, manuscripts, palaeographic comparison and demonstrable transmission. This distinction is important because scripts are powerful identity symbols and therefore especially vulnerable to retrospective continuity claims. Angika's cultural history does not depend on an unbroken proprietary script lineage. Its documented modern writing and print traditions are historically substantial on their own.

41.21 Oral literature as a major archive of the eastern zone

Angika's richest historical archive is not confined to grammar books or modern print. Songs, riddles, proverbs, seasonal repertoires, heroic tales and ritual narratives preserve social vocabulary and regional aesthetics that formal administrative sources rarely record. As argued in Chapter 40, oral materials must be dated at the level of the observed or recorded version. Their importance lies not in proving that every stanza is ancient but in revealing what communities chose to remember, repeat and adapt. Folk literature also travels easily across linguistic borders. A tale may be performed in locally Angika speech, retold in Hindi, or share motifs with Bengali and Maithili traditions. Variation is therefore evidence of circulation rather than a defect. Collecting multiple versions from different places can reveal which episodes are stable, which are local and which appear to have entered through recent media.

41.22 Bihula–Bishahari and Manjusha: language, ritual and visual narrative

The Bihula–Bishahari tradition gives the eastern zone an unusually visible intersection of oral narrative, ritual performance and visual art. Bihar Museum and Government of India craft documentation identify Manjusha painting with Bhagalpur and the Bihula–Bishahari story. The tradition is important linguistically because a narrative does not circulate only through pictures: songs, invocations, explanations, festival speech and artisan vocabulary accompany the material object. Rajiva Kumar Sinha and Om Prakash Pandey's study

likewise treats Manjusha as a route into regional folklore, trade and history. Yet the chronology of the present art form and the chronology of every narrative motif must be kept separate. Modern institutional descriptions sometimes assign very ancient dates; those claims require independent evidence. What can be stated securely is that Manjusha is a documented cultural emblem of the Bhagalpur/Anga region and a living vehicle for Angika-associated oral culture.

41.23 Women, ritual memory and the household transmission of speech

Women's ritual and domestic repertoires are indispensable to Angika social history. Marriage songs, birth songs, snake-goddess observances, laments, teasing songs and household tales transmit forms of speech that may be underrepresented in male-authored print. Patrilocal marriage can also move linguistic features: a bride carries pronunciation, vocabulary and songs between natal and marital settlements, while children learn from several generations of women. Such transmission helps explain why speech boundaries may be porous even where regional identities are strong. The household archive is difficult to date, so field recordings and older folklore collections must be compared carefully. Gender also shapes prestige: a form dismissed as "rustic" in formal writing may remain central to ritual authority. The eastern linguistic-cultural zone cannot therefore be reconstructed from public literary institutions alone.

41.24 Markets, river trade and occupational multilingualism

Market exchange produces a practical kind of multilingualism. Boatmen, grain dealers, artisans, cultivators, traders, transport workers and itinerant specialists need not abandon their home speech to communicate across a region. Instead they develop receptive competence, mixed registers and occupational vocabulary. Bhagalpur's riverine and later rail connections amplified these interactions. Trade terms can move rapidly because they are repeated in transactions, while household grammar remains more stable. The same process operates in fairs and pilgrimage markets, where ritual objects, songs and stories circulate alongside commodities. A linguistic history that ignores commerce will therefore misread borrowing as accidental. The eastern zone's vocabulary and code-switching patterns are partly the sediment of ordinary economic cooperation across communities.

How speech features circulate across the eastern zone

Borrowing, code-switching and convergence are normal products of repeated social contact.

Figure 162 — Social channels of linguistic circulation

41.25 Migration, towns and the widening Angika public

Modern migration has expanded Angika beyond its older territorial core. Education, government service, industrial employment and metropolitan labour create communities in which local speech becomes a portable marker of home. Migration changes language in two directions. Speakers acquire Hindi, Bengali, English or other urban languages, but digital communication also allows them to maintain Angika across distance. In the home region, return migrants bring new vocabulary and styles. This process helps explain why modern Angika can become more consciously named at the same time that individual repertoires become more multilingual. The sociolinguistic unit is no longer a bounded village alone; it includes WhatsApp groups, associations, literary networks and families divided across cities. Historical comparison should therefore distinguish territorial spread from speaker mobility.

41.26 Print, radio and digital codification

Every new medium changes what counts as a standard form. Print requires spelling choices; radio privileges intelligible broadcast pronunciation; keyboards and search systems favour encoded characters and consistent orthography. Angika grammars and online writing communities have proposed ways to represent locally salient vowels and pronunciations within Devanagari. These projects are historically significant even when writers disagree about the best system. Standardisation selects among variants and can create new expectations of correctness. It can also increase accessibility by making teaching material, dictionaries and searchable text possible. The resulting written norm should not be mistaken for a direct continuation of one medieval spelling tradition. It is a modern technological and institutional achievement built on older speech.

41.27 Modern Angika literature and institutions as historical evidence

The twentieth-century expansion of Angika literature provides a dated archive of identity formation. Bibliographic records in Bihar list works such as Abhaykant Chaudhary and Naresh Pandey Chakor's 1977 history of Angika literature, while later writers and organisations produced poetry, fiction, criticism, grammar and journalism. Dr. Amarendra's 1998 prose history is another marker of a self-conscious literary field. Such works matter not only for their content but because their publication demonstrates networks of authors, publishers, readers and cultural organisations. They allow historians to ask when Angika became a durable printed label, which genres were cultivated, and how literary language related to local speech. Claims within regional literary histories still require source criticism, especially when they assign very early texts to Angika, but the existence of the modern literary movement is itself firmly documentable.

41.28 Census, recognition and the politics of naming

Official language categories are never neutral mirrors of speech. A census form, school rule or language schedule may encourage speakers to choose among labels that do not match the fine-grained variety used at home. Conversely, campaigns for recognition can make a previously local name more visible and more widely adopted. Historical statistics must therefore be read together with classification instructions and political context. A rise or fall in the number of people reported under a language name may reflect relabelling as well as demographic change. This is especially important in Bihar, where Hindi, Maithili, Magahi, Bhojpuri, Angika and Bajjika have interacted within changing administrative and literary hierarchies. The historian should separate three questions: what people spoke, what they called it, and what the state allowed them to record. Those answers may differ.

41.29 A source-critical workflow for Angika history

This volume uses a reproducible hierarchy. First, identify the source’s date, place, speaker or author, and its own language label. Second, separate direct linguistic evidence—recordings, specimens, grammars and texts—from retrospective regional claims. Third, map the evidence at the smallest available geographic scale rather than assigning whole districts automatically. Fourth, distinguish genealogical classification from modern identity and official recognition. Fifth, test claims of antiquity through continuous dated witnesses; a shared place-name or script-name is not sufficient. Sixth, compare neighbouring languages to distinguish inheritance from contact. Finally, keep oral, visual and material culture in the analysis without converting them into linguistic proof they cannot provide. This workflow permits a rich history of Angika while reducing the risk of both erasure and retrospective invention.

Evidence firewall: Anga is not automatically Angika

Figure 163 — Evidence firewall: Anga is not automatically Angika

41.30 Conclusion: Angika as language, history and eastern regional field

Angika is best understood through the interaction of three histories. One is linguistic: an eastern Indo-Aryan speech complex with strong historical connections to the varieties that Grierson grouped under Maithili and with sustained contact with Magahi, Bengali and Munda languages. The second is regional: the Bhagalpur–Champa, Munger, Kosi and Santal Parganas corridors formed an eastern cultural field shaped by rivers, markets, ritual and migration. The third is institutional: modern writers, grammarians, organisations and catalogues made Angika a durable public name and literary identity. These histories overlap but are not identical. Keeping them separate allows the volume to acknowledge both the older Chhika-Chhiki/southern-Maithili classification and the modern separate Angika identity without forcing either one backward across all periods. The result is a more precise history of eastern Mithila–Anga: connected, multilingual and continually remade.

Table 41.1 — Evidence domains for Angika and the eastern linguistic-cultural zone

Evidence domain	What it can establish	Principal limit
Dated linguistic survey or specimen	Forms, distribution and classification used at a known historical moment	Survey labels reflect sampling and scholarly frameworks; they are not timeless autonyms

Evidence domain	What it can establish	Principal limit
Modern corpus, grammar or recording	Present speech structure, variation and current naming practices	Cannot by itself establish medieval or ancient usage
Comparative linguistic features	Degrees of structural relationship and possible contact zones	Shared forms may reflect inheritance, borrowing or convergence; chronology must be tested
Regional literary institutions	When Angika became a durable public, printed and pedagogical identity	Modern literary naming cannot automatically reclassify older texts
Oral narrative and performance	Living repertoires, local vocabulary, social memory and transmission routes	The recorded version has a date; every motif need not be ancient
Material/visual culture such as Manjusha	Documented links among place, ritual, craft and narrative practice	Art history is cultural evidence, not direct proof of a language's antiquity
Ancient Anga texts and archaeology	Political geography, settlement and regional historical context	A regional name does not establish the structure or name of a later vernacular
Administrative/census categories	Official recognition and how speakers were counted or labelled	Reported numbers and labels can change through classification policy as well as demography

Chapter 42 — Bajjika and Western Mithila

Bajjika occupies the western side of the linguistic-cultural field examined in this volume, especially the Muzaffarpur–Vaishali–Sitamarhi–Sheohar belt and its continuation into Nepal’s Madhesh. Yet its history cannot be written by beginning with a modern label and simply pushing that label backward. Ancient Vajji/Vr̥ji, medieval western Mithila, Grierson’s Western Maithili, twentieth-century Bajjika literary self-identification, and Nepal’s present census category are connected but not identical objects. This chapter therefore combines historical linguistics, sociolinguistics, census evidence, regional literary history and the social history of mobility. It takes Bajjika identity seriously while distinguishing between the date of a name, the age of a speech feature, the geography of a repertoire and the institutional moment at which a language becomes visible in print, education, statistics or digital media.

42.1 Why western Mithila requires a contact-zone model

The western Mithila plain is not a linguistic island. Muzaffarpur and Vaishali face Bhojpuri-speaking districts to the west, Magahi and Hindi-dominant administrative spaces to the south, central Maithili varieties to the east and north-east, and Nepal’s Madhesh across an international border that is recent compared with the older circulation of people. Speech features therefore travel through marriage, weekly markets, pilgrimage, labour migration, schooling and media. A contact-zone model makes it possible to describe a recognizable Bajjika core without turning every isogloss into a political boundary. It also explains why researchers report internal varieties influenced by Maithili, Bhojpuri or Magahi. The important historical question is not whether contact exists—it plainly does—but which features appear old, which diffuse more recently, and which become socially emblematic only after writers and language activists begin to name them as Bajjika.

42.2 Vajji/Vr̥ji and Bajjika: resemblance is not a chronology

The modern name Bajjika is often linked in public memory to the ancient Vajji or Vr̥ji confederacy centred in the wider Vaishali region. The association has obvious regional power, but historical method requires caution. Ancient Buddhist, Jain and Brahmanical materials can establish Vajji as a political and cultural formation; archaeology can illuminate settlement and exchange around Vaishali. Neither source alone yields a grammar of the everyday speech of the republican age. Between ancient Middle Indo-Aryan stages and modern Bajjika lie many centuries of linguistic change. The name may preserve, revive or reinterpret regional memory, but that possibility must not be converted into automatic proof that a single language called Bajjika existed unchanged from the first millennium BCE. This chapter therefore treats Vajji as historical context and Bajjika as a modern linguistic identity whose deeper genealogy must be reconstructed feature by feature.

42.3 The geography of the modern speech community

Modern descriptions usually place the Bajjika core in north-central Bihar, especially Vaishali and Muzaffarpur, with substantial use in Sitamarhi, Sheohar, Samastipur and adjoining areas and with transition toward the Champaran districts. Kashyap’s sociolinguistic work describes a broader Bajjikanchal and identifies Vaishali–Muzaffarpur as a central or standard area within the modern speech community. Such maps should be read as contemporary ethnolinguistic descriptions, not as medieval territorial charters. They are valuable because they identify where speakers, authors and activists recognize Bajjika today and because

they reveal border zones where neighbouring languages exert strong influence. For historical reconstruction, district names are therefore coordinates for collecting evidence rather than timeless language compartments.

42.4 Grierson and the category “Western Maithili”

The Linguistic Survey of India is indispensable because it provides dated speech specimens and an explicit classificatory framework from the colonial period. Grierson treated western varieties around north Muzaffarpur within the Maithili field and used the label Western Maithili. A 2025 Central Institute of Indian Languages publication likewise correlates modern Bajjika with Grierson’s Western Maithili while mapping several other modern regional names to older survey varieties. This continuity of classification is historically significant, but it does not settle every modern identity question. Colonial surveys classified repertoires according to the comparative categories available to their compilers; later communities may reorganize those categories through literature, schooling, census practice and political self-description. The survey is strongest when used as a dated linguistic snapshot, not as a permanent constitutional ruling on whether Bajjika must forever be called a dialect or a language.

Bajjika and the western Mithila contact zone

A graded contact field explains both distinctiveness and overlap better than a single hard boundary.

Figure 164 — Bajjika and the western Mithila contact zone

42.5 From dialect label to public language name

The twentieth century brought a different kind of evidence: grammars, dictionaries, periodicals, literary gatherings and organizations using Bajjika as a primary name. Awadheshwar Arun, R. N. Sharma, Surendra Mohan Prasad and other scholars participated in the codification of vocabulary and grammar, while Bajjika writers expanded prose, poetry, drama and translation. Codification matters historically because a named language becomes easier to teach, edit, publish, archive and mobilize around. It also changes how speakers hear variation: features previously treated as local speech can become markers of a broader literary community. This is not merely a political afterthought to linguistic structure. Standardization itself is a social process that selects forms, creates norms and defines audiences. The rise of Bajjika as a durable public label is therefore part of the language’s history, even where scholars continue to disagree about its taxonomic relation to Maithili.

42.6 Structural evidence: why Bajjika deserves direct description

A language history cannot be reduced to competing names. Detailed grammatical description shows why Bajjika must be studied on its own terms. Kashyap's work on verb agreement documents a complex system in which agreement can encode person, honorific degree, spatial distance and, under restrictions, gender, and can index more than one participant. Such data demonstrate that the variety is not adequately described by a vague claim that it is simply 'mixed' speech. Direct structural work permits comparison with Maithili, Bhojpuri and Magahi while also identifying patterns that deserve specific analysis within Bajjika. The correct comparative question is therefore not 'Is it really X or Y?' but 'Which innovations, retentions and contact-induced features occur, where, and with what social distribution?' That shift from label dispute to describable structure is one of the most productive developments in recent Bajjika scholarship.

42.7 Honour, distance and social grammar

The unusually rich agreement system described for Bajjika also reveals how grammar can encode social relations. Honorific distinctions and deictic distance are not decorative additions to a neutral linguistic core; they organize choices speakers make about respect, intimacy, hierarchy and reference. For social history, this matters because linguistic structure preserves conventions of interaction that can be compared across generations and neighbouring languages. Yet contemporary patterns cannot simply be projected unchanged into medieval society. The safest use of modern grammar is comparative: it identifies domains—honorification, participant indexing, deixis—in which older texts, early recordings or survey specimens may be checked for continuity or change. Social grammar is therefore evidence about a living system and a guide for historical questions, not a time machine.

42.8 Internal variation is part of the language, not noise

Modern Bajjika scholarship commonly distinguishes a central Vaishali–Muzaffarpur variety from forms influenced by Maithili, Bhojpuri and Magahi near the edges of the speech area. Nepal-based surveys similarly describe eastern, central and western Bajjika zones shaped by neighbouring Maithili and Bhojpuri. These patterns show why a single 'pure' form should not be treated as the only authentic Bajjika. Contact varieties are historical records of mobility and adjacency. At the same time, influence labels must be used carefully: they summarize distributions rather than proving that every feature came from one direction. A rigorous dialect history requires dated recordings, age-graded speakers, lexical and morphosyntactic comparison, and geographic sampling. Variation, properly documented, allows us to reconstruct pathways of diffusion rather than merely to rank speakers by distance from a chosen standard.

42.9 Contact with Bhojpuri on the western edge

The western side of Bajjika meets Bhojpuri across a broad transition belt rather than a single line. Recent work on structural change reports present-tense and auxiliary forms in some Bajjika speech that are not attested in the older comparison used by the researcher and interprets them as relatively recent diffusion from Bhojpuri. Whether every proposed pathway survives future testing, the method is important: current variation is compared with earlier evidence to distinguish inherited structure from newer contact-induced change. This is precisely the kind of chronological reasoning needed for the western Mithila zone. Bhojpuri contact should neither be denied for identity reasons nor exaggerated into the claim that Bajjika is merely eastern Bhojpuri. It is a channel of change within a multilingual frontier.

42.10 Contact with central Maithili to the east

Eastward, Bajjika overlaps structurally and historically with varieties classified as Maithili. The 2025 CIIL corpus project explicitly places Bajjika in correspondence with Grierson's Western Maithili, and Glottolog's current genealogical tree lists Bajjika under Maithili even while an ISO 639-3 code *vjk* is associated with the Bajjika entry. These facts illustrate rather than eliminate the classificatory complexity. Shared inheritance and long contact can make boundaries fuzzy, while literary standardization makes them socially sharper. For this volume, the important point is that Western Mithila contained a continuum with internal centres, not a homogeneous speech block. Modern Bajjika identity and the historical Maithili comparative frame can both be documented without pretending that they are the same type of evidence.

Bajjika classification: the label changes with the institution

Figure 165 — Bajjika classification: the label changes with the institution

42.11 Contact with Magahi and urban Hindi

Southern routes through Hajipur, the Ganga crossings and the Patna metropolitan sphere expose Bajjika speakers to Magahi and to regional and standardized Hindi. Administrative employment, higher education, print, broadcast media and migration have strengthened Hindi as a public-domain language for many speakers. This does not imply replacement of home speech. Instead, repertoires become layered: Bajjika may dominate intimacy and neighbourhood interaction while Hindi is selected for school, formal writing or wider mobility. Code-switching and lexical borrowing are therefore expected. Historical analysis should ask when such domain specialization intensified and which institutions drove it, especially the expansion of mass schooling and electronic media. The result is a multilingual hierarchy rather than a simple sequence in which one language mechanically displaces another.

42.12 Kaithi, Devanagari and the problem of script identity

Speech and script histories must be separated. Western Bihar and Mithila participated in several scribal traditions, including Kaithi in administrative and mercantile contexts and Devanagari in increasingly broad print and educational use. Modern Bajjika publication is overwhelmingly associated with Devanagari, but that does not mean the modern literary standard can be projected directly onto every older Kaithi document from the region. Script tells us about scribal practice, office, literacy networks and genre; language must still

be identified from the text itself. A future manuscript survey of western Mithila should therefore catalogue script, date, place, genre and linguistic features independently. Only then can the history of Bajjika writing be reconstructed without equating a regional script with a single language.

42.13 Oral culture as a major transmission domain

Like the wider Mithila–Vajji–Anga region, western Mithila preserves large repertoires of songs, tales, proverbs, ritual speech and performance. Oral forms are especially important where formal schooling and print historically privileged other languages. They preserve vocabulary, phonology, idiom and social registers that may be underrepresented in administrative documents. Yet the evidentiary rule established in Chapter 40 applies fully here: a song recorded in the twentieth or twenty-first century is a dated performance, not automatically an unchanged medieval text. Variation among performances is itself meaningful because it shows how communities reshape inheritance. Systematic audio archiving with speaker age, locality, gender, performance setting and date would provide an exceptional resource for future Bajjika historical linguistics.

42.14 Women’s domestic speech and invisible archives

Domestic and life-cycle genres often preserve speech forms that formal archives miss. Wedding songs, birth rituals, teasing songs, laments, work songs and women’s narratives circulate through kinship networks and can carry linguistic features across villages when marriage is exogamous. In western Mithila this movement is especially important because marriage networks connect communities across the Bajjika–Maithili–Bhojpuri transition zones and across the India–Nepal border. Such genres are therefore sources for both language and social history, provided that researchers record who performs them and where the performer learned them. The archive of women’s speech should not be treated merely as folklore supplement; it is part of the evidence for how language is reproduced across generations.

42.15 Vaishali and Muzaffarpur as modern cultural centres

Vaishali carries immense ancient prestige, while Muzaffarpur has long served as an educational, commercial and print centre. Their importance to modern Bajjika identity arises from this layered regional centrality, but the layers must not be collapsed. Ancient Vaishali belongs to the history of Vajji and early urbanism; modern Vaishali district and Muzaffarpur belong to contemporary linguistic geography and institution-building. The same place can anchor multiple historical narratives without proving that all of them are continuous in the same way. For Bajjika, the two centres matter because modern scholarship often treats their speech as central or standard and because literary and organizational networks have used them as reference points for broader Bajjikanchal identity.

42.16 Bihar census categories and the problem of counting

India’s census tables record mother tongues through a classification system in which many reported varieties are grouped under larger language headings. The 2011 Bihar C-16 tables are therefore essential evidence for official language statistics, but they do not yield a straightforward Bajjika total comparable to Nepal’s separate Bajjika count. This is a crucial methodological point. Absence of a simple line item does not prove absence of speakers; nor can activist estimates be substituted for census data without explaining their method. A responsible demographic history should distinguish raw self-reported mother tongues, census aggregation rules, linguistic estimates and political claims. Counting is an institutional act, and changes in classification can alter apparent speaker totals even when everyday speech changes more slowly.

42.17 Nepal 2021: Bajjika as a separate census mother tongue

Nepal provides a different administrative picture. The National Population and Housing Census 2021 lists Bajjika separately and records 1,133,764 mother-tongue speakers, or 3.89 percent of the national population. The census language report shows that 99.4 percent of these speakers are in Madhesh Province. These are unusually valuable contemporary data because they document both self-identification and geographic concentration through an official state instrument. They should not, however, be read backward as proof that earlier censuses or historical populations used the same label in the same way. The rise from the 2011 Bajjika count also reflects, at least potentially, changing self-reporting and classification as well as demographic growth. Census history must therefore be read institutionally as well as numerically.

42.18 Rautahat, Sarlahi and Mahottari in the cross-border continuum

Nepal-based linguistic surveys identify major Bajjika use in Rautahat and Sarlahi and extend the eastern transition toward Mahottari. This geography continues the speech continuum north of Bihar without implying uniformity on either side. The international border intersects older routes of marriage, markets, pilgrimage and seasonal movement. Speakers may therefore share forms across the boundary while being educated under different national curricula and exposed to different official languages. Nepal's Nepali-medium state institutions and Bihar's Hindi-dominant public sphere create different patterns of bilingualism around related local speech. Cross-border comparison is consequently one of the best laboratories for separating inherited Bajjika structure from newer state-driven contact effects.

42.19 The India–Nepal border as a sociolinguistic experiment

Because the border divides a related speech area between two national systems, it allows unusually precise questions. Which lexical items diverge because of Hindi versus Nepali schooling? Which honorific or verbal forms remain shared despite state separation? Which scripts, spellings and literary norms converge through digital media? Which local markets preserve older cross-border patterns? Such questions require matched village studies rather than broad claims. The border should therefore be treated as a sociolinguistic experiment produced by history: one speech continuum exposed to different bureaucratic, educational and media ecologies. This approach can illuminate both resilience and change without turning linguistic similarity into a nationalist argument about territory.

One speech continuum, different state classification systems

Administrative categories shape statistics; they do not create the linguistic ecology.

Figure 166 — One speech continuum, different state classification systems

42.20 Literature and the making of a reading public

A language becomes socially different when writers can assume a reading public. Bajjika literary organizations, dictionaries, grammars and creative works helped create that public by making orthography, vocabulary and genre choices visible and repeatable. Modern literature also gives scholars a dated corpus against which spoken variation can be compared. Yet literary standardization inevitably selects. A printed form may privilege Vaishali–Muzaffarpur usage, simplify local variants or adopt Sanskritic and Hindi-derived vocabulary for wider readability. The literary language must therefore be studied as a historical construction rather than mistaken for a transparent transcription of all Bajjika speech. Its achievement is precisely that it turns a variable repertoire into a durable medium of public expression.

42.21 Dictionaries and grammar as institutions of memory

Works such as Bajjika grammars and the Bharati Bajjika Hindi Kosh do more than list forms. They establish headwords, preferred spellings, paradigms and examples; in doing so they preserve lexical memory and influence future usage. Lexicography is therefore an institutional stage in the history of the language. It also provides evidence for what scholars at a particular moment considered representative Bajjika. Historical linguists can compare such works with field recordings and older survey materials to detect change. The risk is circularity: once a dictionary becomes authoritative, later writers may adopt its choices, making them appear older or more widespread than they originally were. Dating the codification process is therefore essential.

42.22 Education, literacy and the mother-tongue question

The debate over mother-tongue education in Bihar is especially sharp in regions where official and literary categories do not align neatly with home speech. Children may arrive at school using Bajjika while textbooks and classroom interaction privilege standard Hindi or standard Maithili. Educational policy therefore becomes part of language history by influencing literacy, vocabulary and prestige. The relevant historical question is not simply which language ‘belongs’ to a district, but what linguistic distance children experience

between home and school and how teachers manage that distance. Locally grounded primers, oral-to-written transition materials and multilingual pedagogy can be discussed without requiring a final taxonomic verdict on the language-versus-dialect question.

42.23 Religion does not map neatly onto language

Western Mithila contains Hindu, Muslim and other communities whose everyday repertoires overlap while also showing community-specific vocabulary and registers. Nepal surveys have noted Muslim-community varieties within the Bajjika field; similar differentiation deserves careful study in Bihar. Persian-Arabic vocabulary may enter through Urdu and religious practice, while Sanskritic vocabulary may be reinforced through ritual, schooling or print. These layers should not be mistaken for separate ethnic languages unless speakers and structural evidence support such a conclusion. Religious identity, caste, occupation and locality intersect with speech, but none provides a one-to-one linguistic boundary. The chapter therefore treats community registers as part of the internal sociolinguistic ecology of Bajjika.

42.24 Migration, remittances and the expanding repertoire

Labour migration to Patna, Delhi, Punjab, metropolitan India, the Gulf and other destinations changes Bajjika repertoires through prolonged contact with Hindi, Urdu, Punjabi, English and other languages. Return migrants bring vocabulary, discourse styles and media habits into village speech. Mobile phones intensify this process by allowing daily contact with home while exposing speakers to national and transnational media. Migration can therefore produce both convergence and renewed local identity: speakers may use more Hindi-derived forms in some contexts while valuing Bajjika more strongly as a marker of home. A future historical corpus should record migration history alongside age and locality, because linguistic change increasingly follows mobility networks rather than simple geographic distance.

42.25 Digital media and the new visibility of Bajjika

Digital publication lowers the cost of creating a public language domain. Social media posts, video channels, digital magazines, songs, comedy and messaging make Bajjika visible outside the institutions of print and formal education. The result is rapid orthographic experimentation and a vast new spoken archive. For researchers, this abundance is both opportunity and problem. Digital material is date-stamped and often geolocatable only imperfectly; speakers may stylize language for humour or identity; platform algorithms reward certain registers. Preservation therefore requires metadata and ethical archiving. Even so, the digital turn is historically significant because it gives Bajjika speakers a space in which naming and usage can reinforce each other at unprecedented scale.

42.26 Why “mixed language” is usually an inadequate explanation

Bajjika is sometimes casually described as a mixture of Maithili and Bhojpuri. Such a formula may capture the listener’s perception of overlapping features but is linguistically too crude. All Indo-Aryan languages share inherited material, and neighbouring varieties also borrow from one another. To call one variety ‘mixed’ without specifying which features were inherited, innovated or borrowed replaces analysis with impression. Kashyap’s grammatical work and later contact studies show that Bajjika has describable internal systems and identifiable pathways of diffusion. The better model is a historically layered language variety within an Eastern Indo-Aryan continuum, shaped by both inheritance and contact. That formulation leaves room for modern autonomous identity without denying deep relations to Maithili and neighbouring languages.

42.27 Language versus dialect: a question with several answers

The language/dialect distinction can refer to genealogy, mutual intelligibility, standardized literature, political recognition, speaker identity or administrative coding; these criteria need not produce the same answer. Bajjika illustrates the problem vividly. Grierson and the 2025 CIIIL framework connect it to Western Maithili; Glottolog places Bajjika under Maithili while recording the Bajjika ISO code vjk; Nepal's census counts it separately; Bajjika authors and speakers may assert an autonomous language identity. These are not necessarily contradictions because they answer different institutional questions. A historical volume should record each classification with its date and purpose rather than forcing all evidence into a single timeless label.

42.28 What would a stronger historical corpus require?

The next major advance in Bajjika history requires a diachronic corpus. It should combine Grierson-era specimens, dated early print, grammars and dictionaries, newspapers, private letters where available, oral recordings from different generations, and contemporary digital speech. Every item should carry locality, date, genre, speaker or author information and, where relevant, script. Comparable corpora should be built for central Maithili, Bhojpuri and Magahi so that apparent Bajjika innovations can be tested against neighbouring evidence. India–Nepal paired sites would be especially valuable. Such a corpus would move the debate from assertion to measurable chronology: which forms appear when, where and in which social domains.

42.29 Evidence hierarchy for writing Bajjika history

The safest workflow begins with dated linguistic evidence: survey specimens, manuscripts whose language can actually be identified, printed texts, recordings and corpora. Next come sociolinguistic sources that document speaker identity, domain use and institutional status. Census data establish official categories and reported populations for a particular year. Regional memory, ancient place names and literary tradition provide crucial historical context but cannot alone establish a modern linguistic form in antiquity. Finally, present-day grammar can guide questions about earlier stages but should not be treated as direct medieval evidence. This hierarchy does not privilege one community's preferred label; it privileges chronological transparency.

Evidence firewall: Vajji is not automatically Bajjika

Figure 167 — Evidence firewall: Vajji is not automatically Bajjika

42.30 Conclusion: Bajjika as western Mithila's historical speech field

Bajjika can be understood most accurately when three histories are held together without being collapsed. The first is genealogical and areal: western Mithila belongs to an Eastern Indo-Aryan continuum with deep connections to Maithili and sustained contact with Bhojpuri, Magahi and Hindi. The second is regional: Vaishali, Muzaffarpur, Sitamarhi, Sheohar and the adjoining Madhesh districts form a social field linked by markets, kinship, migration and ritual. The third is institutional: modern grammars, dictionaries, literature, ISO coding and especially Nepal's census recognition have made Bajjika increasingly visible as a named language. The result is neither an unchanged survival from ancient Vajji nor a mere modern invention. It is a historically layered speech community whose present identity has both inherited linguistic depth and modern institutional form.

Table 42.1 — Evidence domains for Bajjika and western Mithila

Evidence domain	What it can establish	Principal limit
Ancient Vajji/Vrji texts and archaeology	Political geography, settlement, institutions and regional context	Cannot by itself establish the grammar or modern name Bajjika
Grierson-era survey specimens	Dated Western Maithili forms, distribution and colonial classification	A 1903 classification is not a timeless verdict on present identity
Modern grammar and corpus studies	Bajjika structure, agreement, variation and current speech patterns	Present structure cannot automatically be projected into medieval periods
Literature, dictionaries and organizations	The institutional history of Bajjika standardization and public naming	Codified forms may select one variety from a wider continuum
India census tables	Official language counting and aggregation rules in a specific census	No directly comparable separate Bajjika total should be invented from grouped categories
Nepal 2021 census	Separate Bajjika mother-tongue count and provincial distribution	Counts reflect self-reporting and state categories of that census year
Oral and digital recordings	Living speech, genre, variation, code-switching and transmission	Every recorded form has a date; oral survival does not prove unchanged antiquity
Comparative contact evidence	Possible diffusion from Maithili, Bhojpuri, Magahi, Hindi or Nepali	Borrowing must be demonstrated feature by feature and chronologically

Chapter 43 — Sanskrit Learning and Scholastic Institutions

Sanskrit learning is one of the strongest documented strands in the intellectual history of medieval Mithila, but its institutions have often been described with anachronistic vocabulary. This chapter reconstructs the learned world through teachers, pupils, manuscripts, commentaries, courts, debates and mobility. It gives special attention to Gaṅgeśa and Navya-Nyāya while keeping jurisprudence, Mīmāṃsā, grammar and other disciplines in view. It also separates dated evidence from later heritage memory, so that the historical importance of Mithila’s scholastic culture does not depend on calling it a modern-style university.

43.1 Why “institution” must be defined historically

The phrase “scholastic institution” can mislead if it evokes a modern university with a charter, permanent campus, salaried departments and centralized admissions. Sanskrit learning in medieval Mithila was institutionally real, but its durable units were usually different: teacher-households, circles of pupils, manuscript collections, lineages of commentary, courts that rewarded learning, assemblies of experts and reputations that drew students across regions. The historical task is therefore to identify recurring practices and relationships rather than to search for a single building called a university. A text that names a teacher, patron or place; a manuscript copied for study; a sequence of commentaries; and evidence of pupils travelling to a renowned master can together reveal an institution even when no campus archive survives. Conversely, later claims about a continuous “Mithila University” must be tested rather than repeated. This chapter uses “institution” in this distributed sense.

43.2 Sanskrit as a scholastic language inside a multilingual society

Sanskrit did not monopolize speech in Mithila, Vajji or Anga. It functioned as a prestigious language of śāstric argument, ritual learning, legal digests, philosophy, theology and much courtly writing, while everyday communication and large parts of literary performance operated through Maithili and related regional speech forms. Avahatṭa and other literary registers, and later Persian documentary culture, further complicated the ecology. The distinction matters because the social power of Sanskrit depended precisely on this multilingual setting. Students had to acquire a technical register whose vocabulary and syntactic habits were learned, rehearsed and transmitted. A scholastic institution therefore taught more than doctrines: it trained readers to inhabit a specialized language of reasoning. Chapter 36 established the broader pre-standardization ecology; here the focus is on the social mechanisms that reproduced one especially influential learned register within it.

43.3 Earlier precedents: Vācaspati Miśra, Udayana and the problem of local memory

Mithila’s later reputation did not emerge from nothing. Vācaspati Miśra and Udayana stand within the long history of Nyāya, Mīmāṃsā, Vedānta and related Sanskrit argumentation, and later regional memory strongly associates major teachers and sites with Mithila. Yet textual attribution, biographical tradition and the identification of a modern village site are different forms of evidence. The safest historical method begins from datable works and manuscript traditions, then asks how firmly a locality can be connected to them. Vācaspati’s breadth across philosophical systems demonstrates the permeability of disciplinary boundaries;

Udayana's works show the sophistication of Nyāya-Vaiśeṣika argument before Gaṅgeśa. These predecessors are indispensable to the intellectual genealogy of the region, but archaeological or topographical claims about exact “academies” require independent corroboration. The point is continuity of learned problems and methods, not an invented unbroken campus history.

43.4 The teacher-household as a durable educational form

A renowned teacher could create an institutional centre without founding a college in the modern sense. Pupils lived near or with a teacher, copied or memorized texts, listened to exposition, rehearsed objections and replies, and learned how a technical expression was to be deployed. Reputation attracted new pupils; successful pupils carried the method elsewhere; manuscripts and remembered lessons stabilized a curriculum. Such arrangements were economically dependent on household resources, gifts, landed support, court patronage or the contributions of pupils and their families. They were also vulnerable: the death or migration of a teacher could shift an intellectual centre rapidly. This helps explain why medieval scholastic geography is better drawn as a network of nodes than as a map of permanent universities. The institutional ecology depended on people, texts, patronage and travel acting together.

Figure 168 — Sanskrit scholastic life as a distributed institutional ecology

43.5 Gaṅgeśa and the reorganization of Nyāya

Gaṅgeśa, active in Mithila in the first half of the fourteenth century, transformed the scale and style of Sanskrit analytical philosophy through the *Tattvacintāmaṇi*. Modern historians commonly identify the work as the foundational text of Navya-Nyāya, “new” Nyāya, not because earlier Nyāya disappeared but because the techniques of definition, qualification and relational analysis acquired a new precision and became a common intellectual technology. The work is organized around four accepted means of knowledge: perception, inference, comparison and testimony. That architecture made it teachable as a sequence of problems while also inviting commentary at multiple levels. Institutional history is visible here in textual form. A difficult base text produces teachers, glosses, competing readings, abridgements and specialist reputations; the curriculum grows because the text is hard enough to require mediation. Gaṅgeśa’s importance thus lies both in philosophical innovation and in creating an exceptionally productive object of study.

43.6 The four pramāṇa books as a pedagogical architecture

The fourfold organization of Tattvacintāmaṇi around pratyakṣa, anumāna, upamāna and śabda gave teachers a modular but interconnected curriculum. Perception required analysis of cognition, error and conceptualization; inference demanded precise accounts of pervasion, reason and fallacy; comparison raised questions about similarity and recognition; testimony opened onto language, sentence meaning and authority. A pupil who mastered these books did not simply memorize conclusions. The pedagogical ideal was the ability to reconstruct an opponent's position, identify the exact locus of disagreement, formulate a definition that avoided over- and under-extension, and answer counterexamples. Such training explains why Navya-Nyāya techniques later entered jurisprudence, grammar and other śāstric domains. The curriculum was portable because it was encoded in textual problems and methods rather than tied to a single building.

43.7 Technical language as an intellectual technology

Navya-Nyāya's most consequential institutional achievement was a language for making relations explicit. Expressions specifying qualifier, qualificand, locus, delimitor and the mode of a relation allowed scholars to analyze ambiguity with extraordinary granularity. This was not "logic" in the narrow modern classroom sense. It was a disciplined meta-language that could be borrowed by jurists, grammarians and philosophers working on very different objects. Learning that language required sustained apprenticeship because an apparently small change in a compound or relational phrase could alter an argument. Once mastered, however, it enabled communication across teacher lineages. The technical register therefore acted like intellectual infrastructure: it made complex problems comparable, compressible and transmissible. Its diffusion is one of the clearest signs that a scholastic institution can outlive the locality where a method was first developed.

43.8 Commentary as curriculum, research and credential

Commentary was not secondary writing added after the "real" philosophy. In Sanskrit scholastic life, a commentary could be the classroom, laboratory and public demonstration of competence at once. To explain Gaṅgeśa, a scholar had to identify inherited readings, decide where an objection began and ended, reconstruct suppressed reasoning, and show why a preferred formulation survived rival interpretations. Subcommentaries could then turn a single sentence into a new field of dispute. The result was cumulative without being merely repetitive. A pupil's mastery was visible in the ability to enter this chain and make a defensible intervention. The vast post-Gaṅgeśa literature therefore records institutional activity: who was reading whom, which problems had become canonical, and where technical innovations were being recognized. A commentary lineage is thus also a social lineage, although the two should never be assumed to coincide perfectly.

Tattvacintāmaṇi as a scholastic commentary engine

The institution survives through textual operations: teaching a base text, writing on it, contesting it, and transmitting technical vocabulary.

A commentary tradition is therefore simultaneously a literary archive, a curriculum and a network of teachers.

Figure 169 — *Tattvacintāmaṇi as a scholastic commentary engine*

43.9 Manuscripts were working instruments, not passive containers

A scholastic manuscript was handled, corrected, recited, excerpted and compared. Marginal notes, interlinear glosses, colophons and changes of hand can reveal use over time. The physical manuscript therefore belongs inside the history of teaching, not merely in a library appendix. Copying could be pedagogical: writing a difficult text fixed its sequence in memory and forced decisions about segmentation. Manuscript scarcity also shaped pedagogy because a teacher might control access to a small number of exemplars. At the same time, famous stories that Mithila teachers categorically prohibited students from taking copies of logical works away must be treated cautiously. They may preserve a memory of restricted access or local prestige, but they require contemporary corroboration before being used as institutional rules. The secure point is simpler: control of texts mattered because texts were expensive, laborious and intellectually powerful.

43.10 Patronage: courtly support without reducing scholarship to propaganda

Courts mattered to Sanskrit learning because rulers and landed elites could reward scholars, sponsor copying, provide residence, commission digests and attach prestige to debate. Oiniwar-period Mithila offers especially important evidence for interaction between courtly and scholastic worlds. Yet patronage did not make every philosophical argument a piece of royal propaganda. A work on inference or sentence meaning could participate in a centuries-old technical conversation whose standards were set by other scholars. The court's role was often to stabilize the conditions under which such work could be pursued and publicly recognized. Patronage also created inequalities: some lineages gained visibility because their texts were copied and preserved, while others left faint traces. Institutional history must therefore follow both intellectual content and the material conditions that allowed particular forms of scholarship to survive.

43.11 Debate and disputation as public tests of learning

Nyāya had long theorized forms of debate, and medieval scholastic reputation continued to depend on the ability to defend propositions before qualified opponents. Public disputation transformed knowledge into a social event. A teacher's fame could grow through successful argument; a pupil could acquire status by demonstrating control over technical distinctions; courts and assemblies could become stages on which intellectual authority was negotiated. Yet later anecdotes often exaggerate debates into spectacular contests with absolute winners and losers. The historical core is more modest and more significant: a culture of

objection and reply made learning accountable to an expert audience. It also trained scholars to anticipate criticism in writing, which helps explain the nested pūrvapakṣa-siddhānta structure of so many texts. Debate was therefore both pedagogy and quality control.

43.12 Examination traditions: evidence, memory and caution

Regional histories frequently describe śālākā-parīkṣā and other demanding examinations in which a student had to explain a randomly selected portion of a text. Such accounts are plausible within a manuscript-centered scholastic culture and appear in important histories of Indian logic. But the exact dates, procedures and institutional reach of these examinations are not equally well documented. They should therefore be presented as a layered tradition: later scholarly histories may preserve genuine practices, yet each named examination needs chronological anchoring before it can be assigned to every century of medieval Mithila. The broader institutional point does not depend on the most dramatic version of the story. Advanced learning required recognized demonstrations of competence, whether through debate, exposition, teaching, authorship or formal testing. Credentialing existed socially even when its bureaucratic form is uncertain.

43.13 Mīmāṃsā and the hermeneutics of authoritative language

Mīmāṃsā was crucial to the wider learned ecology because it provided sophisticated theories of injunction, sentence meaning, textual authority and action. Gaṅgeśa himself was remembered as a teacher of both Nyāya and Mīmāṃsā, and later intellectual history repeatedly shows movement of concepts across these disciplinary boundaries. For a region whose ritual, legal and philosophical cultures depended heavily on interpreting authoritative Sanskrit texts, hermeneutics was not an isolated specialty. It trained scholars to ask how words generate knowledge, how apparently conflicting passages can be reconciled, and what follows from a prescribed act. These questions entered Dharmaśāstra and later Navya-Nyāya discussions. Institutional specialization therefore coexisted with methodological exchange. A teacher might be famous for Nyāya while expecting pupils to understand Mīmāṃsā distinctions that made the Nyāya argument intelligible.

43.14 Dharmaśāstra and the regional production of jurisprudence

Medieval Mithila was not only a centre of abstract logic. Sanskrit jurisprudence developed regional schools whose arguments about ownership, inheritance and authority interacted with Navya-Nyāya methods. Christopher Fleming's reconstruction of Maithila and Gauḍa jurisprudence shows that these were historically situated intellectual formations rather than timeless "Hindu law" codes. The Maithila/Miśra school developed positions that could differ sharply from other Sanskrit jurisprudential traditions. This is institutional evidence because legal reasoning required communities of readers capable of recognizing a school's vocabulary and authorities. Digests and commentaries connected scholarship to social practice without becoming simple transcripts of everyday custom. They show experts trying to organize normative questions through a shared technical tradition. Chapter 32 treated women, marriage and property from a social-historical angle; here the emphasis is the learned machinery that produced such jurisprudential arguments.

43.15 Candeśvara and the work of compilation

Candeśvara's Sanskrit digests belong to the wider history of Mithila's juristic and political learning. Compilation should not be dismissed as derivative. To build a digest, a scholar had to select authorities, order

topics, reconcile contradictions and decide which inherited rules mattered to a new political environment. Such works reveal the institutional need for usable knowledge: courts, learned households and ritual specialists required texts that could navigate a large śāstric archive. They also show why the distinction between composition and application matters. A digest can tell us what an expert considered authoritative or debatable; it does not automatically tell us how every village dispute was resolved. The compiler stands at the junction of library, classroom and court, making the digest a particularly revealing institutional genre.

43.16 Grammar, semantics and the discipline of exact reading

Nyāya and Mīmāṃsā arguments constantly touched grammar and semantics because philosophical disputes often turned on what a sentence could mean, how reference worked, or whether a property was expressed directly or by implication. The scholastic institution therefore depended on grammatical competence even when grammar was not the teacher's principal specialization. Sanskrit's dense commentarial prose rewarded exact parsing: compounds had to be segmented correctly, case relations recognized and technical terms distinguished from ordinary usage. This linguistic discipline also helps explain the later productivity of Navya-Nyāya as a meta-language. The classroom was training habits of reading as much as transmitting doctrines. Such habits were portable into poetics, jurisprudence, ritual exegesis and theology.

The scholastic field: disciplines overlapped rather than standing in isolation

A scholar could move across disciplines; institutional history should not mistake modern departmental boundaries for medieval ones.

Figure 170 — Overlapping disciplines in the Sanskrit scholastic field

43.17 Ritual, jyotiṣa and practical learned expertise

Not all Sanskrit expertise took the form of philosophical commentary. Ritual specialists, calendar makers, astrologers and scholars of jyotiṣa operated within learned economies that connected textual competence to recurring social needs. Determining ritual times, interpreting calendrical cycles, preparing horoscopes or adjudicating ritual procedure could give a scholar a public role beyond the advanced philosophical circle. The surviving evidence is uneven, and later professional categories should not be projected backward unchanged. Nevertheless, the broader point is secure: Sanskrit learning was sustained because it linked multiple kinds of specialized knowledge to households, temples, courts and life-cycle practices. The scholastic world was therefore socially embedded even when its most celebrated texts appear abstract.

43.18 Access, hierarchy and the danger of retrospective caste projection

Advanced Sanskrit learning was shaped by social hierarchy, especially by gender, lineage, ritual status and access to patrons or teacher households. But the categories used to describe that hierarchy must be period-

specific. In particular, this project does not project “Śrotiya” backward as a fixed medieval Maithil Brahmin sub-caste; the Panji-based chronology adopted in this volume places its emergence as a distinct sub-caste around 1800 CE. Medieval scholarly titles, ritual reputations and lineages therefore cannot simply be translated into later sub-caste labels. The same caution applies to assumptions that every person called paṇḍita, miśra or upādhyāya occupied an identical social position. Institutional history should reconstruct access from contemporary evidence rather than making a later social taxonomy do medieval work.

43.19 Women and the limits of the scholastic archive

The surviving Sanskrit scholastic archive is overwhelmingly male-authored and male-genealogized. That fact is evidence about preservation and institutional access, but it should not be inflated into proof that women possessed no learned agency. Women could participate in elite households, ritual economies, patronage and vernacular knowledge transmission even when advanced śāstric authorship remained difficult to document. The correct historical response is neither to invent female philosophers to fill a gap nor to treat archival silence as total social absence. Instead, the chapter marks the asymmetry and asks where other evidence might survive: donor records, manuscript ownership notes, household correspondence, vernacular narratives or later family histories. The gendered shape of the archive is itself an institutional fact.

43.20 Knowledge villages, scholarly households and spatial clustering

Mithila’s intellectual geography is often narrated through villages associated with famous paṇḍitas. Some associations may rest on strong genealogical or textual evidence; others survive mainly through local memory, place names or commemorative sites. Spatial clustering is historically plausible because pupils benefit when several teachers, manuscript owners and debating partners live within travelling distance. Marriage and kinship could further stabilize scholarly lineages. Yet a modern memorial mound or “dih” should not be treated as self-authenticating proof of a medieval academy. The strongest map is layered: one symbol for sites securely named in manuscripts or dated texts, another for early historical testimony, and another for later memory. Such a map would reveal an intellectual landscape without pretending that all points carry equal evidentiary weight.

43.21 Oiniwar Mithila and the density of learned culture

The fourteenth to sixteenth centuries stand out because political, literary and philosophical evidence converges on Mithila as a dense centre of Sanskrit learning. Pankaj Jha’s study of the fifteenth-century literary world emphasizes the vibrancy of this milieu, while histories of Navya-Nyāya document major teachers and commentary traditions. Court patronage, local scholarly households and regional mobility reinforced one another. The resulting culture was not purely Sanskritic: Maithili literary production, Avahaṭṭa, ritual performance and growing interaction with Persianate political forms coexisted with śāstric work. This is precisely why “Sanskrit learning” should be understood as one powerful institutional strand in a multilingual society rather than as a total description of culture.

43.22 The later Vidyāpati Ṭhakkura inside the scholastic-courtly world

Within this project’s governing two-Vidyāpati framework, the fifteenth-century Vidyāpati Ṭhakkura belongs to the Oiniwar-associated world of Sanskrit and Avahaṭṭa composition, documentary practice and courtly knowledge. Works conventionally associated with this later figure, including Kīrtilatā, Kīrtipatākā, Puruṣaparīkṣā, Gorakṣavijaya and Likhanāvalī, are therefore discussed as evidence for a learned environment in which Sanskrit expertise interacted with political ethics, scribal practice and vernacularizing literary forms.

This profile must not be conflated with the earlier Mahākavi Vidyāpati of the Maithili Padāvalī tradition adopted elsewhere in this volume. The distinction is methodologically important in Chapter 43 because otherwise the history of scholastic institutions would be made to rest on a composite biography rather than separately analyzed historical contexts.

43.23 Pakṣadhara and the mature commentary culture

Pakṣadhara Miśra, also known in the Navya-Nyāya tradition as Jayadeva, represents the mature phase of Mithila's post-Gaṅgeśa commentary culture. His work on *Tattvacintāmaṇi* became a major point of reference, and later histories connect his teaching reputation with students from Bengal. The significance is not biographical celebrity alone. A scholar becomes institutionally important when later authors must position themselves relative to his readings. Commentary creates a chain of intellectual obligation: a pupil may reject a teacher's argument yet still transmit the framework in which the disagreement makes sense. That mechanism explains how a local teaching centre can generate a transregional school.

43.24 Student mobility between Mithila and Bengal

By the late medieval period, the history of Navya-Nyāya cannot be written within one region. Traditions of scholars travelling from Bengal to study with Mithila teachers, followed by the growth of Navadvīpa as a major centre of logic, indicate a powerful east-Indian corridor of intellectual mobility. The exact biographies of individual students require source criticism, especially when later narratives supply dramatic details. But the larger shift is well supported by the literary history of the school: texts, technical vocabulary and problems associated with Mithila became central to Bengal's scholastic institutions. Mobility did not simply transfer a finished package. Students and later commentators transformed what they learned, creating new centres of authority.

43.25 Raghunātha Śīromaṇi and the problem of heroic biographies

Raghunātha Śīromaṇi's later fame makes him a magnet for stories about precocious intelligence, arduous travel and intellectual victory. Such narratives are culturally valuable because they show what later communities admired in a scholar: memory, wit, disciplined reasoning and success in debate. But heroic biography is not the same as a contemporary register. Historians should separate securely datable works and teacher-commentary relationships from anecdotes whose earliest textual witnesses may be much later. Doing so does not diminish Raghunātha's importance. It clarifies the mechanism by which institutional memory turns scholarship into exemplary life stories. The legends themselves become evidence for the social prestige of logic.

43.26 From Mithila to Navadvīpa: relocation, not disappearance

Older histories sometimes describe a "decline" of Nyāya in Mithila as Navadvīpa rose. The language of decline can obscure what actually moved. A major centre of innovation and commentary became increasingly associated with Bengal, but Sanskrit learning in Mithila did not vanish. Jurisprudence, ritual studies, grammar, philosophy and later scholastic traditions continued. Intellectual geography is dynamic: one discipline can shift its leading commentarial centre while teacher households and manuscript cultures remain active elsewhere. The more accurate model is redistribution. Methods developed in Mithila became part of a larger eastern Indian scholastic world and were elaborated in new settings.

43.27 Nepal and the preservation-circulation interface

The Nepal connection matters to scholastic history in at least two ways. First, political and literary networks linked Mithila and the Nepal Valley during the medieval period, creating routes along which scholars, patrons and texts could move. Second, Nepalese manuscript collections have preserved materials crucial to the history of Sanskrit and Maithili literature. Preservation geography, however, must not be mistaken for composition geography: a manuscript found in Nepal may copy a work composed elsewhere, and a Mithila text may survive only because it travelled. Chapter 39 established this distinction for scripts and manuscripts; the same evidence rule governs scholastic institutions.

43.28 Anga and Vajji in the wider Sanskrit knowledge network

The documentation for Sanskrit scholastic institutions is densest for Mithila proper, especially in the Nyāya and jurisprudential traditions. Anga and the Vajji zone participated in the same wider Gangetic networks through pilgrimage, courts, monasteries, markets and routes of manuscript circulation, but the evidence should not be made artificially symmetrical. A responsible regional history states where the archive is strong and where it is thin. Bhagalpur-Champa, Vaishali and other centres have long intellectual histories, yet Chapter 43 does not invent a parallel Navya-Nyāya academy merely to balance the map. Instead, it asks how Sanskrit texts and specialists travelled across the broader region and where future manuscript or epigraphic work could refine that picture.

43.29 An evidence hierarchy for reconstructing a school

A strong reconstruction begins with dated or datable texts, manuscripts, colophons and explicit teacher-pupil references. Next come contemporaneous or near-contemporaneous court records, inscriptions and cross-references in other authors. Later scholastic histories and genealogies are valuable when their claims can be checked against this earlier evidence. Local heritage memory, commemorative sites and oral traditions are important for the history of remembrance but should not silently supply dates that the earlier archive lacks. The same hierarchy applies to institutional practices: a named examination, prohibition or academy should be dated from evidence, not from the antiquity of the tradition that now tells its story.

Evidence firewall for reconstructing scholastic institutions

Best reconstruction = convergence among independent evidence types.

Tradition may guide research, but it should not silently replace dated evidence.

Figure 171 — Evidence firewall for reconstructing scholastic institutions

43.30 Conclusion: a distributed institution of precision

Mithila's Sanskrit scholastic achievement is best understood as a distributed institution of precision. Its strength lay not in a single university bureaucracy but in the durable interaction of teachers, pupils, manuscripts, commentaries, patrons, debates and mobile reputations. Gaṅgeśa's *Tattvacintāmaṇi* became a curricular engine because it generated problems that demanded teaching and produced further writing. Navya-Nyāya methods crossed into jurisprudence and other disciplines; courtly and household support gave scholars material footholds; travel linked Mithila with Bengal and Nepal; and later memory converted famous lineages into regional heritage. This model explains both resilience and change. A centre could move without the tradition disappearing, and a text could become more institutionally powerful as it travelled farther from its place of composition. The history of learning is therefore a history of relations sustained across generations.

Table 43.1 — Evidence domains for Sanskrit learning and scholastic institutions

Evidence domain	What it can establish	Principal limit
Dated texts and colophons	Authorship, copying, patrons, places and chronology when explicit	A surviving copy may be later than composition; silence is not proof of absence
Commentaries and subcommentaries	Curriculum, problems considered canonical, intellectual succession	Textual dependence does not always equal direct teacher–pupil contact
Teacher–pupil references	Mobility, pedagogy and scholarly networks	Later genealogies may compress or idealize relationships
Court records and patronage	Material support, commissions, public status of scholars	Patronage does not determine every argument in a technical work
Manuscript materiality	Use, correction, copying, ownership and circulation	Preservation place is not automatically composition place
Debate and examination traditions	Norms of public competence and credentialing	Named procedures require independent chronological anchoring
Local sites and heritage memory	History of remembrance; clues for field research	A memorial site cannot date itself or prove a medieval academy
Cross-regional textual reception	Movement from Mithila to Bengal, Nepal and beyond	Reception history must not erase regional transformation

PART VI

MATERIAL CULTURE AND THE ARTS

Chapters 44–51

Chapter 44 — Architecture and Settlement

Architecture in Mithila, Vajji and Anga survives unevenly. Massive brick ramparts, stupas, monasteries, rock-cut shrines and temple fragments are visible; timber houses, thatch, fences, workshops and periodic markets are far less so. This chapter therefore joins architecture to settlement archaeology. It asks how water, rivers, routes, fortification, religious institutions, craft production and political authority organized built space, and it keeps excavated sequence separate from legendary or retrospective identification. The result is a social history of built landscapes rather than a catalogue of monuments.

44.1 Architecture as social history, not a catalogue of monuments

Architecture records labour, resources, political authority, religious practice and everyday habits in material form. Yet the surviving record of Mithila, Vajji and Anga is uneven. Monumental brickwork, fortifications and religious structures are more likely to survive than timber houses, thatched roofs, fences or temporary market sheds. A history based only on standing monuments would therefore exaggerate the architectural weight of elites and institutions. This chapter treats architecture together with settlement: where people lived, how water and routes shaped habitation, how defensive works reorganized space, how monasteries and temples concentrated resources, and how ordinary building materials disappeared through rebuilding and floodplain erosion. The central method is archaeological rather than typological. A plan, wall, mound, tank or sculptural fragment is interpreted first in its excavated or documented context. Later tradition may preserve valuable memory, but a legendary name does not automatically establish the original function or date of a structure.

44.2 The alluvial plain as an architectural environment

North Bihar and the adjoining Tarai are difficult landscapes for durable settlement. Rivers migrate, floodplains accrete and erode, high water tables complicate excavation, and brick can be robbed repeatedly for later construction. These processes affect both how people built and what archaeologists can recover. Raised habitation, embankment-like edges, drainage, tanks and the selection of relatively stable ground were practical responses to water risk. At the same time, rivers were not simply hazards. They supplied transport corridors, fisheries, silted agricultural land and connections to markets. The architectural history of the region therefore cannot be separated from hydrology. A settlement that appears isolated on a modern road map may originally have been oriented toward a river channel that later shifted. Conversely, a large mound beside a present river cannot be assumed to have had the same relationship to water in antiquity. Reconstructing settlement requires geomorphology as well as masonry.

44.3 Preservation bias: earth, timber and thatch versus brick and stone

The everyday built environment was probably dominated for long periods by materials that survive poorly. Earth walls can slump into indistinct layers; timber posts leave only stains or post-holes; bamboo and thatch usually vanish; floors may be renewed until earlier surfaces are difficult to isolate. Fired brick, stone thresholds, terracotta plaques and substantial ramparts survive more visibly and therefore attract disproportionate historical attention. This preservation bias is especially severe in wet alluvial conditions. It means that absence of a stone house is not evidence for architectural poverty, and the survival of a temple wall is not proof that religious buildings occupied most of the built landscape. Archaeological interpretation must work from traces of surfaces, hearths, drains, storage, craft debris and spatial organization as well as

from walls. Figure 172 summarizes this filter: what survives most clearly is not necessarily what most people inhabited most of the time.

Architecture survives through a preservation filter

Settlement history must reconstruct the missing everyday fabric, not equate survival with original importance.

Figure 172 — Architecture survives through a preservation filter

44.4 Settlement archaeology and the problem of historical names

Ancient and medieval place-names often outlive the physical arrangements to which they once referred, while modern villages may preserve, relocate or reinvent older names. The problem is acute in famous landscapes such as Mithila and Vaishali, where literary and religious memory is exceptionally strong. Historical geography therefore requires several steps: identify the archaeological mound or structural complex; establish its occupational sequence; compare inscriptions, coins and datable artefacts; and only then evaluate textual or traditional names. The procedure protects the history from circular reasoning. A place is not dated because a story names it, and a story is not proved ancient because a modern mound carries the same name. This does not diminish local tradition. On the contrary, it makes tradition itself a historical source whose chronology can be studied. The distinction becomes essential at sites associated with palaces, assemblies, royal capitals or epic figures, where later commemoration can easily be mistaken for excavation.

44.5 Vaishali as a long-lived settlement landscape

Vaishali provides one of the clearest examples of a settlement whose archaeological life extends across many political and religious phases. Excavations and protected remains include fortification, stupas, monasteries and foundations, while artefacts range across early historic and later periods. The importance of this evidence lies less in assigning every structure to a famous event than in demonstrating repeated occupation and spatial investment. Defensive works were repaired; religious monuments accumulated; water and circulation routes helped sustain habitation; later communities reused earlier spaces. Such continuity complicates any attempt to draw a single “plan of ancient Vaishali.” What archaeology reveals is a palimpsest. The settlement was not frozen in the republican age, and later Gupta, post-Gupta and medieval activity must be allowed its own history. This long duration also explains why structural remains from different centuries can stand close together without belonging to one architectural programme.

44.6 Raja Vishal ka Garh: fortification before political identification

The mound known as Raja Vishal ka Garh is frequently connected in popular description with an ancient assembly. Archaeologically, the more secure observation concerns fortification. Recent excavation across its ramparts, as summarized by the Archaeological Survey of India, has identified multiple defence-wall phases assigned to the Śuṅga, Kuṣāṇa and early Gupta periods, while finds from the broader site extend from the early historic era into much later centuries. This is substantial evidence for a defended and repeatedly used enclosure. It is not, by itself, proof of the precise constitutional function of every enclosed structure. The distinction is important. Fortification tells us about labour mobilization, boundary-making and investment in protected space; political texts may suggest forms of assembly; but the two evidence streams must converge before a specific building can be named an assembly hall. Architectural history is strongest when it resists the temptation to turn a secure wall into an insecure institution.

44.7 Stupas, monasteries and the making of sacred settlement

Buddhist monuments around Vaishali show how sacred architecture could reorganize settlement space. A relic stupa drew memory, pilgrimage and maintenance to a fixed point; monasteries required cells, water, storage, access and support from surrounding producers. Such complexes were not architecturally isolated from the economy. Construction demanded brick-making, transport and specialized labour; continued occupation required food and repair; pilgrimage created routes and periodic concentrations of people. Over time, sacred sites could survive even when surrounding settlement patterns changed. Their visibility today can therefore distort the ancient balance between religious and domestic architecture. The appropriate question is not merely where the stupa stood, but what network allowed it to function. Religious building becomes social history when connected to donors, craftsmen, agricultural surplus, roads, river crossings and the practical routines of residents and visitors.

44.8 Balirajgarh: a fortified site and the value of construction sequence

Balirajgarh in Madhubani district is one of the region's most important fortified archaeological sites. The Archaeological Survey of India's 1962–63 excavation is especially useful because it documented construction rather than relying on the site's traditional name. High groundwater prevented excavators from reaching natural soil, but sections through the defence wall revealed a mud-brick core with brick encasement and several phases of reinforcement and repair. The wall was battered rather than vertical, a practical choice for a massive earthen-brick defence. This sequence demonstrates sustained investment in fortification and changing engineering responses. It does not settle every question about the settlement's identity or political status. Proposals equating Balirajgarh with an ancient capital remain hypotheses to be tested against chronology, material culture and regional settlement patterns. Its strongest contribution to this chapter is architectural: earth and fired brick were combined to create large defensive works on the alluvial plain.

44.9 Fortification as labour, authority and risk management

A rampart is not simply a military object. Building and maintaining a large wall requires organized labour, access to earth or brick, planning of gates and drainage, and decisions about what space is worth enclosing. Fortification can therefore indicate political concentration even when the name of the ruling authority is uncertain. It also reflects risk: warfare, raiding, control of trade, prestige competition or the need to manage movement through gateways. In flood-prone country, raised defensive works could interact with drainage and topography, although such hydraulic functions must be demonstrated site by site rather than assumed. Comparing Balirajgarh, Vaishali and Simraongarh shows why one label cannot explain all walls. Their dates,

materials and settlement contexts differ. The meaningful comparison concerns construction sequence, enclosed area, gate organization and relation to occupation, not a generic category of “fort.”

44.10 Village architecture: the largest missing archive

Most people did not live inside monumental complexes. They lived in villages and dispersed settlements whose architecture was frequently rebuilt with perishable materials. The ordinary house compound may have included sleeping rooms, kitchens, cattle spaces, grain storage, courtyards, fences and work areas whose archaeological signatures are subtle. Seasonal repair could erase earlier wall lines while preserving the continuity of a household plot. Because such remains are less spectacular, they are often underrepresented in published architectural histories. Ethnographic observation of later Mithila compounds can suggest questions—about courtyards, gendered work spaces, thresholds or cattle—but it cannot be projected unchanged into the medieval period. Archaeology must establish each feature independently. The most responsible reconstruction therefore accepts uncertainty: the monumental record is detailed, while the domestic record is fragmentary, even though domestic architecture formed the numerical majority of the built environment.

Settlement as a connected ecological system

Figure 173 — Settlement as a connected ecological system

44.11 Brick economies and standardization without uniformity

Fired brick is one of the most persistent architectural materials of the middle and lower Ganga plains. Its use implies clay extraction, moulding, fuel, firing, transport and skilled laying, and therefore links buildings to an economy of production. Brick dimensions can contribute to chronology when measured in secure contexts, but they should not be used mechanically: reused bricks, local variation and repairs complicate typological dating. Large religious and defensive projects could stimulate production on a scale far beyond household building. At the same time, brick architecture was not uniform. Mud mortar, lime plaster, terracotta facing and stone architectural members could be combined differently according to function and period. The social question is therefore not whether a society “knew brick,” but who could mobilize enough labour and fuel to use it extensively, and how the resulting structures were maintained or cannibalized by later settlements.

44.12 Anga's riverine and rocky architectural zone

The eastern zone of Anga differs materially from the flatter northern plains. Around Bhagalpur and Kahalgaon, the Ganga interacts with rocky outcrops and hills, creating architectural possibilities not available everywhere in Mithila. The Archaeological Survey of India records a monolithic rock-cut shrine in Bhagalpur district, tentatively placed no later than the ninth century, as well as rock sculptures and cave features in the wider district. Such remains demonstrate that regional architecture was not exclusively brick-built. Stone could be carved in situ where geology permitted, while the river connected these sites to wider routes. This variation cautions against imagining a single "Mithila style" extending mechanically across Mithila, Vajji and Anga. Material culture follows geology as well as political history. A social history of architecture must therefore compare subregions before synthesizing them.

44.13 Vikramshila: a planned monastic complex in Anga

The excavated remains at Vikramshila near Antichak provide the clearest large-scale architectural plan in the Anga zone. The Archaeological Survey of India describes a square monastery with 208 cells arranged around a courtyard and a central cruciform stupa; excavation also revealed gateways, votive structures and a building interpreted as a library. This plan is important because it spatially organizes a resident scholarly community. Cells, circulation, worship and teaching were integrated within a single complex, while the surrounding landscape supplied food, water, labour and transport. The monument therefore joins architectural and intellectual history: Chapter 17 treated learned communities, while this chapter asks how architecture made such communities physically possible. Vikramshila also warns against treating institutions as disembodied texts. Manuscripts, teachers and ritual required walls, roofs, storage, pathways and continual maintenance.

44.14 The central stupa and the choreography of movement

The cruciform stupa at Vikramshila structured movement as well as vision. Its central position within the monastic square made it an architectural focus from multiple directions. Circumambulatory paths, projecting chambers and terracotta decoration transformed religious practice into patterned movement through built space. Such architecture did not merely contain ritual; it choreographed it. The relationship between cell and stupa also created a daily spatial rhythm between residence and devotion. Similar questions should be asked of other religious sites even when plans are less complete: where did worshippers enter, what route did they follow, what could they see, and which spaces were restricted? Architecture becomes historically meaningful when plan is translated into action. The spatial discipline of a monastery differed from that of a market, fort or household, and those differences reveal distinct forms of community.

44.15 Terracotta as architecture, image and social archive

Terracotta plaques at Vikramshila remind us that architectural surfaces can preserve social imagery. Decorative programmes may include religious figures, animals, hunting scenes and other motifs that bring elite, devotional and everyday themes into the same visual field. Terracotta is especially important in brick-building regions because it allows moulded or carved surface articulation without requiring abundant building stone. Yet a plaque is not a photograph of ordinary life. Its scenes are selected, stylized and placed within a religious architectural programme. Their value lies in the conjunction of material, imagery and location. Clay, firing and attachment techniques belong to craft history; iconography belongs to religious and artistic history; placement on a stupa belongs to architectural history. Treating these together avoids separating "art" from the built environment that gave it meaning.

44.16 Temple architecture and the danger of survivor typologies

Temples in the region survive in radically different states: standing buildings, rebuilt shrines, isolated stone images, architectural fragments and remembered sacred places. A modern temple may occupy an old sacred site while incorporating little or none of the earlier fabric. Conversely, a medieval image may have been moved from its original building. Typological study of śikhara, doorway, moulding or plan can be useful, but only when the surviving element is securely contextualized. Vijayakanta Mishra's survey of Mithila art and architecture collected many regional examples and remains valuable as a descriptive starting point, yet archaeological dating and fabric analysis must control historical claims. The chapter therefore treats temples as layered sites. Ritual continuity, architectural continuity and sculptural continuity may coincide, but they are not the same thing.

44.17 Stone sculpture without standing temples

The abundance of stone religious sculpture in parts of Bihar and Mithila does not imply that equally numerous stone temples once stood intact. Images could be housed in brick shrines, transferred during rebuilding, recovered from fields or tanks, or reused in later structures. This distinction is essential because art history often preserves objects more successfully than architecture. A sculpture's style may provide a relative date, but its present shrine may be much later. The architectural historian must therefore record provenance carefully: excavated location, reported findspot, current location and any evidence of reuse. The same rule applies to doorjambs, pillars and carved blocks. Spolia can reveal the existence of earlier building traditions while simultaneously obscuring their original plans. Material survival is a chain of movements, not a frozen site inventory.

44.18 Water architecture: tanks, ponds, wells and settlement durability

Water structures are among the most socially consequential forms of architecture in the region. Tanks and ponds supplied drinking water, livestock, ritual needs, fisheries, bathing and sometimes construction material from excavated clay. Their embankments also reorganized neighbourhood space. In a monsoon climate, the challenge was not simply obtaining water but storing, draining and separating uses. Archaeological attention to tanks can reveal settlement planning that monumental surveys miss. At Vikramshila, water was integrated with the monastic complex; at other settlements, ponds became anchors of habitation and sacred geography. Later maintenance can preserve a water body while transforming its banks, so present form cannot be assumed ancient. Nevertheless, the persistence of water features makes them important clues for long-term settlement stability. A history of architecture that excludes ponds and drains would omit some of the most heavily used constructed spaces.

44.19 Roads, river crossings and the architecture of movement

Settlements depend on movement. Gates, ghats, ferries, raised paths and market streets connect architecture to regional exchange. On the Ganga and its tributaries, river crossings could be more important than land roads; seasonal changes in water level altered routes and landing places. The archaeological signature of a road is often faint compared with a wall, yet the orientation of gates, mounds and religious sites can suggest circulation patterns. Historical texts and later route surveys may help, but route continuity must be tested rather than presumed. Figure 173 treats settlement as a node within flows of water, food, labour, ritual and exchange. This network approach prevents the architectural plan from being read as a self-contained object. A monastery without supply routes, a market without access, or a fort without controlled movement is only half explained.

44.20 Markets and periodic public space

Not all important spaces were permanently monumental. Weekly markets, fairs and festival grounds could concentrate thousands of people while leaving limited architectural residue. Temporary stalls, bamboo structures and open grounds are archaeologically elusive, yet they were central to exchange and public culture. Their locations were shaped by route intersections, river crossings, shrines and administrative centres. Later chapters will treat fairs and markets directly, but here the architectural point is methodological: permanence is not equivalent to social importance. Periodic public space challenges a monument-centred history because its infrastructure may consist of paths, shade, water access and customary plot arrangements rather than walls. When a settlement is reconstructed, open space must therefore be treated as positive evidence, not as an empty remainder between buildings.

44.21 Simraongarh: fortified urbanism in the India–Nepal borderland

Simraongarh in the Nepali Tarai is indispensable to the medieval architectural history of Mithila. Archaeological investigations by the Department of Archaeology of Nepal and an Italian mission documented a large fortified urban site through surface survey, stratigraphic sections, ceramics and scientific sampling. The work is especially valuable because the investigators emphasized that chronology remained open to revision rather than forcing all deposits into a single dynastic narrative. Simraongarh's scale, defensive works and dense archaeological landscape nevertheless demonstrate substantial urban investment in the borderland associated with Karnata power. Its position also makes a wider point: political and architectural history cannot be divided neatly by the modern India–Nepal boundary. Materials, artisans, courtly practices and religious networks moved across the Tarai long before the present frontier.

Four archaeological windows on architecture and settlement

Do not force one settlement type onto the whole region.

Compare what was defended, how movement was organized, and which activities were spatially concentrated.

Excavated plan, chronology and function must be evaluated separately at each site.

Figure 174 — Four archaeological windows on architecture and settlement

44.22 Simraongarh chronology and the discipline of uncertainty

A famous capital attracts precise stories, but archaeology often produces ranges, phases and unresolved sequences. The Simraongarh investigations explicitly noted disturbance, re-excavation and the preliminary nature of early radiocarbon and ceramic evidence. That caution should be retained. Dynastic history can provide a chronological frame for Karnata rule; archaeological layers can date occupation and rebuilding; neither should be made to say more than it can support. The appropriate question is how the fortified urban

landscape developed through time, which sectors were occupied, how the ramparts changed, and how the settlement related to surrounding routes and rural production. This discipline of uncertainty is a strength, not a weakness. It keeps future excavation capable of changing the narrative rather than forcing new evidence into an inherited story.

44.23 Courts, palaces and the problem of architectural attribution

Courtly centres must have included residences, audience spaces, storage, service quarters and defensive or ceremonial boundaries, yet palaces are often among the most confidently named and least securely demonstrated structures in later local tradition. A mound called a *rājā's* palace may indeed preserve elite occupation, but the identification requires excavation or documentary convergence. Timber superstructures and repeated rebuilding further complicate recovery. Rather than inventing palace plans, social history can proceed from firmer evidence: concentration of prestige goods, unusually substantial foundations, defensive placement, inscriptions, or texts that securely name a courtly location. The later Vidyāpati Thakkura's documentary and courtly world, discussed in Chapters 35 and 38, presupposes material settings of administration and patronage, but those texts do not automatically identify surviving walls. Literary court and excavated palace must remain separate until evidence joins them.

44.24 Karnata and Oiniwar settlement without dynastic determinism

The Karnata and Oiniwar periods altered political centres, patronage networks and learned institutions, but settlement change cannot be inferred mechanically from changes of dynasty. Villages continued across political ruptures; markets could grow for ecological or commercial reasons; religious sites could outlast their patrons. Chapter 33 reconstructed social economy from multiple evidence streams, and the same principle applies here. Architecture should be tied to dated building episodes and settlement phases, not assigned to a dynasty merely because the dates overlap. Simraongarh provides strong material evidence for a major Karnata-associated urban centre; elsewhere the record may be thinner. Oiniwar courtly culture can be studied through texts and patronage, but precise architectural attribution remains a separate question. This protects the volume from converting political chronology into an architectural template.

44.25 Sacred clusters and settlement nucleation

Temples, monasteries, shrines, tanks and pilgrimage routes can attract settlement around them, but the direction of causation varies. A shrine may be founded at an existing settlement, or settlement may intensify around an established sacred centre. Sacred clusters also accumulate chronologically: an old image, a rebuilt temple, a new pavilion and a modern road may coexist in one precinct. The historian must disentangle these layers. In Mithila, where sacred geography is dense and living traditions are strong, the temptation to treat a present cluster as a single ancient complex is particularly risky. Architectural survey should therefore document fabric, repairs, inscriptions, reused pieces and local narratives separately. The result is richer than a simple date because it reveals how communities continually remake sacred space.

44.26 Craft production and the built environment

Architecture depends on craft sectors that often leave their own settlement signatures. Brick kilns, lime preparation, carpentry, metalworking, pottery and terracotta production require fuel, water, raw material and work space. Large building projects can concentrate artisans temporarily or create durable craft quarters. Conversely, craft production may occur at settlement edges because of smoke, fire risk or access to clay. Archaeological waste—wasters, slag, kiln debris, unfinished pieces—can therefore be as informative as

finished monuments. The artistic surfaces of Vikramshila presuppose a technical infrastructure of clay preparation, moulding and firing; fortified walls presuppose mass earthmoving and brick supply. Material culture becomes social history when these invisible labour systems are restored to the narrative.

44.27 Housing, gender and household work: what architecture can and cannot show

Domestic space structured cooking, childcare, storage, craft, animal care and privacy, all of which had gendered dimensions. Yet the archaeological record rarely labels a room “women’s space” or “men’s space.” Functional interpretation must therefore proceed from installations, artefact concentrations, access patterns and comparative evidence rather than stereotype. Later ethnographic house forms can generate hypotheses about courtyards or secluded zones, but they cannot be projected unchanged into early or medieval periods. This is particularly important in a region where modern social classification has often been read backward. Architecture may reveal differential access and work areas, but social identity must be independently established. The chapter therefore uses domestic space to ask questions rather than to manufacture certainty.

44.28 Settlement hierarchy: hamlet, village, market, monastery, town and capital

Historical landscapes contain settlements of different scales and functions. A large fortified site should not make surrounding villages disappear from analysis, and a monastery may function as a major economic node without being a city in the same sense as a political capital. Settlement hierarchy can be reconstructed through site size, density, craft specialization, imported goods, fortification, institutional architecture and route position. The categories are analytical, not rigid. A village can acquire a market; a shrine can generate a town; a political centre can shrink while remaining sacred. Figure 174 compares four sites precisely to resist a single model. Vaishali, Balirajgarh, Vikramshila and Simraongarh preserve different combinations of defence, residence, ritual and institutional planning. Their differences are historically productive.

44.29 Archaeological method: survey before reconstruction

Future research on Mithila–Vajji–Anga architecture will benefit most from systematic landscape survey tied to excavation, remote sensing, ceramic study, archaeobotany and geomorphology. The region contains many mounds and reused architectural fragments whose relationships remain poorly understood. Mapping site distributions can clarify route corridors and settlement hierarchies before spectacular identifications are proposed. Scientific dating should be prioritized where secure samples exist; brick and ceramic typologies should remain anchored to stratigraphy; oral history should be recorded as evidence of memory and site use. The key methodological principle is convergence. Figure 175 formalizes the evidence firewall used throughout this volume: excavated sequence, standing fabric, texts or inscriptions, and living tradition must be distinguished before they are combined. This approach leaves room for discovery and protects the narrative against inherited certainty.

Evidence firewall for architectural history

Best identification = convergence among independent evidence types.

A traditional name may guide excavation, but it cannot by itself date a wall, palace, assembly hall or temple.

Figure 175 — Evidence firewall for architectural history

44.30 Conclusion: built landscapes as changing social systems

Architecture and settlement in Mithila, Vajji and Anga were products of ecology, labour, authority, religious practice and exchange. The alluvial plains favoured continual rebuilding and erased much domestic fabric; fortified sites such as Vaishali and Balirajgarh reveal large investments in protected space; Vikramshila demonstrates how a planned monastic complex organized residence, worship and learning; Simraongarh places medieval urbanism across the modern India–Nepal border; the Bhagalpur zone adds rock-cut and stone traditions to a predominantly brick-built history. No single architectural style or settlement type defines the region. What unites the evidence is adaptation: to rivers, materials, routes, institutions and changing political economies. The most reliable history therefore begins from construction sequence and spatial function, then connects them to social life. It does not begin from a famous name and search for walls to fit it.

Table 44.1 — Evidence domains for architecture and settlement

Evidence domain	What it can establish	Principal limit
Stratified excavation	Construction sequence, rebuilding, occupation and abandonment	Limited exposure may not represent the whole settlement
Ramparts and walls	Material, engineering, enclosed space and labour investment	Function and political attribution require separate evidence
Brick dimensions and masonry	Technical practice and relative chronology when stratified	Reuse and local variation can mislead typological dating
Domestic traces	Floors, hearths, storage, posts and activity areas	Perishable construction is easily erased or under-excavated
Religious complexes	Spatial organization of ritual, residence and patronage	Monument survival can exaggerate religious share of built space
Water structures	Storage, drainage, ritual use and neighbourhood organization	Present form may reflect repeated later repair
Routes, gates and ghats	Movement, market access and controlled circulation	River migration can shift original relationships
Texts and inscriptions	Names, patrons, functions and dates when explicit	A literary place-name does not identify a surviving wall by itself

Evidence domain	What it can establish	Principal limit
Local tradition	Memory, sacred continuity and clues for field research	Tradition is not self-dating archaeological proof
Regional survey	Settlement hierarchy, clustering and route corridors	Surface visibility varies with cultivation and geomorphology

Chapter 45 — Dress, Textiles and Ornament

Dress history in Mithila, Vajji and Anga survives through an unequal archive. Cloth normally decays, while stone beads, shell bangles, terracotta ornaments, production tools, sculpture and words endure. This chapter therefore reconstructs clothing and adornment by triangulating archaeology, art and text, with a chronology firewall against projecting later fashions or the modern reputation of Bhagalpur silk backward into periods for which continuity has not been demonstrated.

45.1 Dress as material culture and social history

Dress is not a decorative appendix to social history. Cloth, jewellery, hairstyles and bodily adornment connect production, gender, labour, status, ritual, climate and exchange. In Mithila, Vajji and Anga, however, the archive is radically uneven: textiles themselves rarely survive in the humid alluvial environment, while beads, bangles, shell, terracotta and stone images survive far more readily. A historically responsible chapter must therefore resist reconstructing a complete costume from a single sculpture or a later ethnographic custom. The task is to combine archaeological small finds, images, texts and evidence for production while keeping the date and social setting of each source visible.

45.2 The preservation problem: cloth disappears, ornament survives

Most garments were made from organic fibres that decay quickly unless preserved in exceptional conditions. Their absence from excavated deposits does not mean that textile production was unimportant; it means that the evidentiary burden shifts to tools, impressions, textual vocabulary and visual representation. Jewellery has the opposite bias. Stone beads, shell bangles, terracotta pendants and metal objects can survive for centuries, making adornment appear more archaeologically prominent than cloth. The resulting archive must be read as a preservation filter, not a direct inventory of what people valued or wore in proportion to surviving objects.

The archive is richest where the original costume is most incomplete.

Figure 176 — Dress survives through an unequal archaeological filter

45.3 Fibres, fabrics and the danger of naming local production

South Asian texts and later material studies identify cotton, silk and wool among major textile fibres, and the early-fourteenth-century Varna-ratnakara names a wide range of fabrics and fine stuffs. Yet a named cloth

in a Mithila text does not prove that its fibre was grown, spun, woven and finished locally. Some fabrics could have been imported as finished goods; others could have arrived as yarn or raw material. The safest reconstruction therefore distinguishes fibre vocabulary from production geography. Local production must be established from tools, occupational evidence, workshop traces, fiscal records or repeated documentary references rather than from a literary list alone.

45.4 Spinning as the archaeological doorway into textile production

At Vaishali and related excavated contexts, spindle whorls and other small objects are especially valuable because they point to textile production without requiring the cloth itself to survive. A spindle whorl indicates spinning activity, but it does not by itself identify the fibre, the gender of the spinner, the scale of production or whether the work served a household or market. These distinctions matter. Spinning could be dispersed through households even where weaving was more specialized, and archaeological tools can move between contexts through reuse or dumping. The evidence is therefore strongest for the presence of fibre-processing activity, weaker for the organization of the labour that produced it.

45.5 Vaishali: beads, bangles and the archaeology of adornment

Excavation reports from Vaishali provide unusually concrete evidence for personal adornment. Finds include bangles and beads made from terracotta and several stones, shell or conch objects, ear ornaments, pendants and related small finds. Such materials demonstrate that adornment was not dependent on precious metal. They also show a spectrum of production in which inexpensive moulded or fired objects could coexist with semi-precious stones and more costly materials. The archaeological record thus cautions against equating jewellery with elite wealth alone. Adornment could be socially widespread even when materials, workmanship and quantity varied sharply.

45.6 Bead materials and exchange networks

Crystal, agate, carnelian, amethyst and other stone beads reported from Vaishali make adornment relevant to trade history. Some raw materials had to move across substantial distances before being shaped or worn. A bead therefore has two histories: the social history of the body and the economic history of material circulation. Yet provenance must not be guessed from colour or stone name alone. Without compositional analysis and production debris, archaeology may not show where a bead was drilled or polished. The secure conclusion is that ornament connected Vaishali to wider material networks, not that every finished object was produced at the site.

45.7 Shell and conch: riverine plains linked to wider ecologies

Shell bangles and conch objects are important because their raw material is not generated by the inland alluvial plain in the same manner as clay. Their presence therefore points toward exchange and specialized working. Shell may have carried ritual meanings as well as decorative value, but not every fragment can be assigned a ritual function. The same material could be shaped into ornaments, containers, ritual objects or other implements. Where shell jewellery occurs with stone and terracotta adornment, the assemblage reveals a material hierarchy more complex than a simple division between precious and non-precious objects.

45.8 Terracotta ornament and the economics of imitation

Terracotta could reproduce the visual effect of more costly materials at a fraction of their material cost. Earrings, beads, bangles and pendants in fired clay show how ornament could be multiplied through

moulding and local manufacture. This does not mean terracotta was merely a poor substitute. Colour, surface treatment, shape and symbolic form could give clay objects their own aesthetic value. The larger historical point is that fashion and bodily display were not restricted to metal-rich elites. Technologies of replication allowed visual styles to circulate more broadly than precious materials themselves.

45.9 Metals and precious materials: wealth, ritual and preservation bias

Gold, silver, copper alloys and gemstones occupy a disproportionate place in literary descriptions and museum collections because they were valuable, durable and often preserved as ritual deposits or curated objects. Their survival can exaggerate elite visibility. Metal ornaments could be melted, recast, stolen or inherited, so archaeological absence may reflect recycling rather than poverty. Conversely, the presence of a precious object at a sacred site may record donation rather than ordinary dress. The chapter therefore treats precious ornament as evidence of wealth and ritual economies only when find context supports that interpretation.

Textiles were processes, not only finished garments

Archaeology may preserve only one or two stages of this life cycle.

Figure 177 — Textiles as a production, circulation and reuse cycle

45.10 Terracotta figurines: dress seen through stylized bodies

Terracotta figurines from Vaishali include figures with applied jewellery, heavy earrings, breast chains, hip chains and elaborate head treatment. Such images are a valuable visual archive, but they are not photographs. Figurines may embody religious, auspicious, erotic or conventional types, and artisans could exaggerate ornaments that needed to remain legible at small scale. The correct use of the evidence is comparative: repeated forms can reveal what kinds of bodily adornment were visually intelligible, while excavation context and chronology help constrain the interpretation. They cannot establish how frequently a particular ornament was worn in everyday life.

45.11 Gupta and post-Gupta sculpture: drape, body and convention

Stone sculpture from eastern India between the Gupta and Pala phases shows a changing visual vocabulary of draped cloth, girdles, scarves and jewellery. Works from Bihar and adjoining eastern regions help situate Mithila-Vajji-Anga within a broader artistic field. Yet divine and courtly images often idealize the body and costume. Transparent or clinging drapery can be an artistic convention rather than a literal record

of fabric technology. Art history is most useful here when it identifies regional and chronological conventions, then tests them against texts and archaeological objects instead of reading sculpture as direct ethnography.

45.12 Pala-Sena sculpture as a visual archive of textiles and ornament

The Pala-Sena schools of eastern Indian sculpture provide abundant evidence for how artists represented lower garments, scarves, belts, necklaces, armlets, anklets and elaborate headdresses. Shahanara Hussain's study of Pala material culture and Susan Huntington's corpus of sculpture show that Bihar formed a major part of this artistic world. The evidence is particularly strong for visual combinations: a long lower garment held by a girdle, scarves looped around the body, and layered jewellery. The limitation is equally important. Many surviving images are deities or bodhisattvas, so sacred iconography and idealized splendour may outweigh ordinary practice.

45.13 Draped garments and stitched garments should not be treated as opposites

Older costume histories sometimes narrate Indian dress as a simple transition from unstitched drapery to stitched garments. The evidence is more complicated. Draped lower garments, scarves, belts and stitched upper garments could coexist, and their social meanings changed by region, occupation and political contact. A sculpted dhoti-like lower garment does not demonstrate the absence of tailored clothing elsewhere in the same society. Conversely, a textual word that resembles a tunic cannot establish universal adoption. The historical question is one of repertoires and combinations, not a single evolutionary sequence.

45.14 Girdles, belts and the architecture of dress

Belts and girdles appear repeatedly in visual representations because they organize draped cloth and create a visible boundary at the waist. They could also become ornament in their own right through clasps, beads and pendants. In sculpture, however, the line between functional fastening and jewellery is often deliberately blurred. A richly carved girdle may belong to the iconographic language of abundance. Archaeological finds of metal fittings would provide a different class of evidence, but such objects are rarely as contextually clear as sculpted examples. Functional interpretation must therefore remain cautious.

45.15 Jewellery by body zone: a system rather than isolated objects

Necklaces, ear ornaments, armlets, bangles, waist chains and anklets form a system of bodily display. Texts from medieval Mithila and sculpture from eastern India use several of these zones repeatedly, but the same body map can carry different social meanings. An anklet might mark beauty, gender, ritual condition or elite display in one source and simply appear as an artistic convention in another. The strongest reconstruction therefore maps ornament by body zone while resisting the temptation to assign a fixed caste, marital or religious meaning across centuries.

45.16 Gender and adornment: evidence before stereotype

Women are often more heavily associated with jewellery in later ethnography and literary convention, but archaeological and sculptural evidence also shows richly adorned male figures. Deities, bodhisattvas, rulers, attendants and performers may all wear substantial ornament. This matters because modern gender expectations can distort the reading of older images. The archive should first establish who is represented, in what context and with what object; only then should gendered meaning be inferred. The same caution

applies to widowhood, marriage markers and ritual restrictions: later normative practices must not be projected backward without period evidence.

45.17 Courtly splendour and the problem of elite over-representation

Courts generated texts, monuments and luxury objects, so elite dress is much easier to recover than the clothing of cultivators, craft workers or servants. Varna-ratnakara's city and courtly descriptions preserve vocabulary of fine cloth and expensive goods precisely because such things belonged to a literary world of urban abundance and distinction. This makes the text valuable for consumption history but incomplete as a survey of society. Elite wardrobes can demonstrate access to variety, imported goods and specialist finishing; they cannot be used as the normal costume of the region as a whole.

45.18 Varna-ratnakara as a lexical archive of cloth and consumption

Jyotirishvara's early-fourteenth-century Varna-ratnakara is indispensable because it names many fabrics, fine stuffs and categories of urban material culture. The text brings together literary convention and observed social vocabulary, including textiles, ornaments, luxury goods and occupations. Some fabric terms remain difficult to identify precisely, and the work often arranges words for rhetorical usefulness rather than economic statistics. Its greatest value is therefore lexical: it demonstrates the existence of a differentiated vocabulary of cloth and consumption in the learned Maithili world. It does not by itself reveal production quantities, prices or the exact geographical origin of every fabric.

Three archives must correct one another

Figure 178 — Three archives for reconstructing dress and ornament

45.19 Local, imported and named fabrics: categories are not provenance maps

Medieval textile vocabularies often distinguish cloths by place-name, quality, weave, material or social association. Such names can outlive the original production centre, just as modern commodity names often travel. A fabric described as foreign or regional may have been copied locally; a "country" cloth may include imported yarn. Consequently, the linguistic category of a textile must not be converted automatically into a trade route. Provenance requires corroboration from merchant records, fiscal documents, production tools or chemical analysis. The distinction is especially important in a borderland connected to Bengal, the middle Ganga plain and Nepal.

45.20 Dyeing, finishing and the invisibility of colour

Colour was central to dress but is one of the least stable features in the archaeological record. Texts can preserve colour vocabulary and references to dyeing, while sculpture can preserve patterned carving but rarely the original colour of cloth. Even when pigment survives on an image, it need not reproduce textile colour. Dyeing, washing, calendaring, printing and embroidery therefore belong to a largely invisible finishing economy. Their historical reconstruction depends more heavily on textual and comparative craft evidence than on surviving garments. This is another reason to avoid presenting monochrome stone sculpture as if it represented monochrome clothing.

45.21 Labour organization: household skill, specialists and markets

Textile production can be divided into fibre preparation, spinning, weaving, dyeing, finishing, tailoring, washing and trade, but historical societies did not necessarily assign each stage to a separate hereditary group. Some tasks may have been household labour; others required specialists or market concentration. The material record at Vaishali confirms at least some spinning-related activity, while medieval lexical sources suggest differentiated cloth production and consumption. The exact organization of labour remains less secure. A responsible social history therefore reconstructs processes first and named communities only where sources actually identify them.

45.22 Anga and silk: a chronology firewall for Bhagalpur

Modern Bhagalpur is famous for silk, and early modern evidence documents silk and textile commerce in Bihar. That later prominence is important, but it cannot be projected automatically into the ancient or medieval Anga landscape. Pala-period sculpture, riverine trade and a later silk industry do not by themselves create an unbroken local weaving genealogy. Chapter 82 addresses Bhagalpur silk as a documented modern and post-independence economy. In the present chapter, Anga's earlier textile history is reconstructed only from evidence securely dated to the period under discussion. The rule is simple: continuity is a conclusion to be demonstrated, not a premise supplied by modern reputation.

45.23 Textile exchange across the Ganga, Bengal and Nepal corridors

The region's river systems and overland routes connected Mithila and Anga to Bengal, the middle Ganga valley and Nepal. Fine cloth could travel easily relative to its value, making textiles well suited to long-distance exchange. Literary references to varied fabrics are consistent with such connectivity, but the direction and volume of specific flows are often unknown for the medieval period. Trade history must therefore combine cloth vocabulary with broader evidence from markets, political routes and later commercial records, while keeping the chronological gap visible. The existence of exchange networks is secure; the itinerary of every named cloth is not.

45.24 Climate, season and layered clothing

The humid monsoon climate of the plains encourages light and washable clothing for much of the year, while winter conditions and travel toward the Himalayan foothills create demand for warmer layers. Varnaratnakara's seasonal descriptions remind us that clothing was not static across the calendar. Yet climate cannot name garments. It can explain why layered, draped or easily laundered cloth might be practical, but only texts and images can indicate historically specific forms. Seasonal reasoning is therefore contextual rather than identificatory: it helps explain choices already attested by evidence, not invent clothing that the archive has not shown.

45.25 Ritual dress and sacred images

Dress can mark ritual state through clean cloth, colour, garlands, sacred threads, monastic robes or special ornaments, but the evidence varies by religious tradition and period. Sacred images often exaggerate ideal costume because adornment itself is devotional. A deity covered with jewellery is not evidence that human worshippers dressed identically. Conversely, monastic ideals of simplicity do not mean that monasteries were isolated from textile economies: robes had to be produced, donated, washed and replaced. Ritual dress thus links religious institutions to household and market production while remaining distinct from everyday costume.

45.26 Marriage, gift and the circulation of ornament

Jewellery and cloth are particularly suited to life-cycle exchange because they combine value, portability and bodily visibility. Medieval normative and literary sources show that marriage was an important arena of property transfer, but the exact composition of gifts varied by status and time. It is safer to treat textiles and ornaments as movable wealth that could circulate through marriage, inheritance and ritual than to impose a later standardized dowry inventory on the medieval period. The same object could be adornment, savings, family memory and transferable property at once.

45.27 Children, workers and the people missing from costume history

Most costume histories are reconstructed from elite art, normative literature and preserved valuables. Children, agricultural labourers, boatmen, craft workers and poor households are therefore under-represented. Their clothing may have been simpler, more frequently repaired and less likely to enter texts or collections. Terracotta ornaments and inexpensive beads help correct that bias by showing that adornment could exist outside precious-metal economies. Even so, absence of evidence remains substantial. A complete social history must make missing populations visible as an evidentiary problem rather than filling the gap with modern rural costume.

45.28 Repair, reuse and the long life of cloth

Textiles are unusually recyclable. A garment can be patched, cut down, passed to another person, converted into household cloth, used as wrapping or finally reduced to fibre and waste. This long use-life reduces the amount of discarded textile likely to enter archaeological deposits. Jewellery is similarly mobile: metal can be melted and stones reset. Material culture therefore has biographies rather than single moments of use. Reuse also complicates dating, because an old bead may be deposited in a much later context. Archaeological association and wear patterns are crucial for distinguishing production date from final deposition.

Figure 179 — Chronology firewall for textile history

45.29 Method: triangulating object, image and word

No single source can reconstruct the dress history of Mithila, Vajji and Anga. Archaeology supplies materials and production traces but rarely complete garments. Sculpture and terracotta show how cloth and ornament were visualized but are shaped by iconography. Varna-ratnakara and other texts preserve terminology but select for literary and elite worlds. Later trade records document textile economies but cannot be pushed backward automatically. The strongest method is triangulation: a claim gains confidence when different archives converge at a compatible date. Where they diverge, the disagreement should remain visible rather than being solved by preference.

45.30 Conclusion: clothing as a mobile archive of society

Dress, textiles and ornament reveal a society in motion. Fibres moved through spinning and weaving; fabrics moved through households, markets, courts and ritual exchange; beads and shell linked bodies to wider material networks; texts transformed cloth into social vocabulary; sculpture transformed it into visual convention. Vaishali provides durable evidence for adornment and spinning-related activity, Pala-Sena art supplies a rich but elite and sacred visual archive, and Varna-ratnakara records a differentiated textile world in medieval Mithila. Taken together, these sources show variety without requiring false continuity. The history is strongest when each object, image and word remains anchored to its own time.

Table 45.1 — Evidence domains for dress, textiles and ornament

Evidence domain	What it can establish	Principal limit
Vaishali small finds	Beads, bangles, shell, terracotta ornaments and spinning-related activity	Rarely preserves the complete garment or identifies the wearer
Terracotta figurines	Visible jewellery zones, hairstyles and stylized bodily display	Miniature conventions and ritual or auspicious types may exaggerate features
Gupta / Pala-Sena sculpture	Drapery, scarves, girdles, jewellery combinations and elite visual conventions	Sacred and idealized images are not direct records of everyday dress

Evidence domain	What it can establish	Principal limit
Varna-ratnakara	Fabric vocabulary, fine stuffs, consumption categories and urban material language	Literary lists do not prove local production, quantities or universal use
Medieval social-history texts	Courtly consumption, gifts, status and occupational context	Elite and normative viewpoints over-represented
Early modern textile trade	Later circulation of silk and cotton through Bihar and Bengal	Too late to prove medieval continuity without intermediate evidence
Modern Bhagalpur silk	Documented regional industry and identity	Must not be projected backward into ancient Anga or the Pala period

Chapter 46 — Food History of Mithila, Vajji and Anga

46.1 Food history is an evidence problem before it is a cuisine story

A history of food in Mithila, Vajji and Anga cannot begin by copying a modern recipe list backward into antiquity. Food is unusually vulnerable to historical distortion because cooked dishes disappear almost completely, while modern regional cuisines are vivid and familiar. The reliable sequence is the reverse: begin with charred plant remains, animal bones, fish and shell, grinding stones, hearths, ovens and vessels; then add dated texts, inscriptions and institutional records; only after that use later ethnography to test possible continuities. This chapter therefore distinguishes ingredients from dishes, production from consumption, and memory from dated evidence. A grain recovered from an archaeological layer proves cultivation or use more securely than it proves a named recipe; a medieval food-name proves vocabulary and social practice more securely than it proves an unchanged dish across centuries.

46.2 The alluvial ecology behind the regional food system

The food history of the region was shaped by an alluvial landscape of monsoon rainfall, rivers, flood basins, ponds, wetlands and fertile but mobile soils. Such an environment favoured rice but never supported rice alone. Winter cultivation, pulses, oilseeds, livestock, fish, molluscs, fruits and collected plants broadened the subsistence base and reduced dependence on a single harvest. Floods could replenish soils and aquatic resources, yet they could also destroy standing crops, grain stores and transport routes. Food security therefore depended on seasonal diversity, storage, social exchange and access to different ecological niches. The contrast between north Bihar's flood-prone plains, the Ganga corridor and the eastern Anga zone helps explain why household diets combined field agriculture with riverine and wetland resources rather than forming a narrowly cereal economy.

46.3 Chirand as a regional comparator, not a substitute for Mithila

Chirand lies in north Bihar on the Ganga and is one of the richest regional archaeological comparators for prehistoric food history, but it must not be treated as if it were a direct excavation of every part of Mithila, Vajji or Anga. Its Neolithic deposits nevertheless demonstrate the range of resources available in the broader middle-Ganga environment. Archaeological and zoological studies report rice, wheat, barley, pulses and field pea, together with domesticated cattle, buffalo, sheep, goat and pig and a wide spectrum of wild and aquatic fauna. Fish, turtle and molluscan remains matter especially because they show that wetlands and rivers were active food-producing zones. Chirand therefore supplies a model of mixed subsistence against which evidence from sites within the book's core regions can be compared, with geographical distance always stated rather than concealed.

46.4 Rice: central crop, contested beginnings

Rice is indispensable to the food history of the middle Ganga plain, yet its earliest chronology remains debated. Archaeobotanical research has recovered early rice from several Ganga-plain sites, but scholars continue to distinguish between wild collection, cultivation and fully domesticated rice. The debate is important methodologically: the presence of rice grains or phytoliths is not automatically equivalent to settled paddy agriculture, and very early dates require secure stratigraphy and morphological evidence. By the later Neolithic, Chalcolithic and early historic phases, however, the importance of rice within the regional crop system is much more secure. For Mithila, Vajji and Anga, the safest historical conclusion is therefore not

that a single timeless rice cuisine existed from the first appearance of rice, but that wet-rice cultivation became one of the durable agricultural foundations from which many later food traditions could develop.

Figure 180 — How food history survives: an evidence hierarchy

46.5 Crop diversification and the two-season advantage

Archaeobotanical work across the Ganga plain shows that rice coexisted with barley, wheat, millets, pulses and oil-bearing crops. The significance is not merely dietary variety. A combination of monsoon and winter crops spreads labour and risk across the year and links food history directly to agricultural scheduling. At sites such as Chirand and Senuwar, rice was complemented by winter cereals and pulses; broader Ganga-plain datasets add mung bean, field pea, lentil and several millets. This diversification complicates any picture of an exclusively rice-eating population. It also suggests differentiated preparations: whole grains, ground flour, boiled pulses, parched cereals and mixed dishes would have demanded different processing tools and fuel regimes, even where the exact recipes are archaeologically unrecoverable.

46.6 Pulses, oilseeds and the hidden architecture of everyday meals

Pulses and oilseeds are less visually spectacular than monuments, but they are central to nutritional and economic history. Archaeobotanical assemblages from the Ganga plain include mung, lentil, peas, sesame and mustard among other taxa. Pulses complement cereal diets with protein; oilseeds provide cooking fat, condiments and marketable produce. Their presence also changes how we imagine rural labour because threshing, drying, storage and grinding varied by crop. Later regional food systems make extensive use of pulses and mustard oil, but the historical argument must move in stages: archaeological occurrence demonstrates ancient or early use of ingredients, while continuity of particular preparations must be shown through dated textual or ethnographic evidence rather than assumed from present practice.

46.7 Fish, rivers and wetlands as food-producing landscapes

Fish is often treated as a cultural preference, but archaeology first reveals it as an ecological opportunity. Chirand has yielded fish remains, and the riverine geography of the Ganga plain created repeated access to

fish, turtles, molluscs and other aquatic resources. Such foods could be caught seasonally, consumed locally, dried or otherwise preserved, although preservation methods are difficult to reconstruct without direct evidence. The importance of aquatic resources would have varied by household, religious discipline, social status and proximity to water. The evidence therefore supports a long history of fishing and aquatic consumption in the wider region without licensing the claim that every community, caste or religious institution shared the same diet.

46.8 Cattle, buffalo, sheep, goat and pig: animals beyond a simple meat/no-meat binary

Faunal remains from regional sites show domesticated cattle, buffalo, sheep, goat and pig alongside wild species. Bones can demonstrate the presence and sometimes the butchery of animals, but animal economies were multifunctional. Cattle and buffalo supplied traction, manure and milk as well as potential meat; sheep and goats supplied milk, hair or fibre as well as flesh; pigs had a different economic niche. Religious and normative traditions increasingly shaped what kinds of animal consumption were valorised, restricted or condemned, but archaeological deposits remind us that practice was neither uniform nor reducible to later vegetarian/non-vegetarian identities. A social history must therefore ask who controlled animals, which products were extracted during an animal's lifetime, and under what circumstances slaughter occurred.

46.9 Wild animals, hunting and the shrinking visibility of foraging

Neolithic and Chalcolithic assemblages in Bihar include deer and other wild animals in addition to domestic stock. Hunting and gathering did not vanish at the moment agriculture appeared. Wild meat, fruits, greens and wetland foods could supplement cultivated staples, especially in seasons of shortage or among communities with specialised ecological knowledge. Over time, expanding cultivation, settlement, political control over forests and changing ritual norms could alter access to wild resources. Because later elite texts often privilege cultivated food and courtly or ritual cuisines, archaeological faunal evidence is especially important for recovering the older mixed economies that textual sources may understate.

46.10 Hearths, ovens, querns and pottery: reconstructing cooking without recipes

Cooking technologies preserve a different history from ingredients. Hearths and ovens demonstrate controlled heat; querns, mullers and grinding stones reveal the transformation of cereals and pulses; pottery shapes suggest boiling, storage, serving and transport. At Chirand, reports of hearths and ovens have encouraged interpretations of roasting and communal feeding, though such functional readings should remain tied to context rather than treated as certain recipes. Ceramic form, soot and residue can narrow possibilities, but a pot is not a named dish. The strongest reconstruction therefore moves from action to cuisine cautiously: pounding, grinding, boiling, roasting, frying and fermentation are technical processes whose combination into specific regional foods requires additional evidence.

Figure 181 — Alluvial food system: season, field and water

46.11 Early historic towns and the problem of feeding non-farmers

The growth of Vaishali and other early historic centres changed food history by separating many consumers from direct cultivation. Officials, artisans, merchants, monks, travellers and urban households depended on grain moving from rural producers into markets, institutions and domestic stores. Urbanisation therefore increased the importance of transport, measurement, storage and exchange. Archaeology can document settlement size, storage-related vessels and market connectivity more readily than daily menus, but the economic implication is clear: feeding towns required recurring surplus and distribution networks. Food became a commodity as well as a subsistence good.

46.12 Vaishali: market, hospitality and institutional consumption

Vaishali's importance in Buddhist and Jain traditions makes it one of the best places to observe how food crossed household, market and religious boundaries. Narrative sources repeatedly present donors providing meals, groves or hospitality to religious communities, while archaeology confirms a substantial settlement and long occupation. These narratives should not be mined as literal menus, yet they demonstrate that cooked food, alms and hospitality carried social and religious meaning. A meal could convert agricultural surplus into merit, prestige and alliance. The city therefore belongs in food history not because one can reconstruct a single "Vaishali cuisine," but because it reveals the institutional circulation of food among householders, merchants, elites and renunciants.

46.13 Buddhist alms and the difference between monastic rules and regional cuisine

Buddhist monastic literature regulates the receipt, timing and acceptability of food, but such rules describe institutional discipline rather than the complete cuisine of Vajji or Anga. Monks depended on lay producers and donors, so the alms economy connected religious institutions to local agriculture and markets. Rules concerning meal times, stored food or prohibited forms of acquisition illuminate the social

organisation of eating more securely than they identify a regional recipe. At large monasteries such as Vikramshila in the Anga zone, collective feeding must have required substantial provisioning, but the excavated architecture does not by itself reveal a detailed menu. The historical point is scale, dependence and redistribution, not culinary invention.

46.14 Jain discipline and food as an ethical problem

Jain traditions associated with Vaishali and the wider region place exceptional emphasis on non-violence, restraint and the ethical consequences of taking life. These disciplines affected which foods could be accepted, how food was obtained and the moral status of eating. Yet monastic prescriptions should not be projected onto all lay households or treated as a census of local practice. Their value for food history lies in showing that diet had become an explicit field of ethical reflection: choices about plants, animals, preparation and timing could express religious identity. The coexistence of such disciplines with archaeological evidence for diverse animal use also illustrates why normative and material sources must remain analytically distinct.

46.15 Milk, curd and ghee: products of a mixed agro-pastoral economy

Cattle and buffalo economies make dairy historically plausible long before particular regional combinations appear in texts. Milk can be consumed fresh or transformed into curd, butter and ghee, extending shelf life and concentrating value. Dairying also links food to gendered and household labour, animal ownership and market exchange. By the early fourteenth century, Jyotirisvara's *Varna-ratnakara* gives much firmer regional evidence for curd and cream in feast description. This is the point at which a historian can move from the general economic possibility of dairying to specific medieval Mithila food vocabulary.

46.16 Sugar, jaggery and sweetness

Sweetness in historical diets came from several sources, including fruits and processed sugarcane. Sugarcane has a long history in northern and eastern India, but the scale and technology of processing varied. Boiling cane juice into jaggery, producing more refined sugar, and using sweeteners in ceremonial foods required fuel, vessels and specialised labour. Medieval feast vocabulary and later market records show that sweets became socially important, but the survival of a modern sweet cannot establish its medieval form. The safer historical method is to trace sweetening agents, processing technologies and named preparations separately.

46.17 Fruit, gardens and seasonal abundance

The alluvial plains supported orchards and garden produce as well as field crops. Mango, jujube and other fruits occur in textual, archaeobotanical or later historical evidence, while Buddhist narratives famously make groves in the Vaishali region part of landscapes of donation and hospitality. Fruit could be eaten fresh, dried, pickled or transformed, though exact techniques must be dated separately. Gardens were also status-bearing spaces: access to cultivated fruit linked food to landholding, urban leisure and religious patronage.

46.18 Salt, spices and the geography of things not grown locally

Food history also includes ingredients that had to travel. Inland north Bihar did not produce every salt, spice or aromatic substance consumed there. Trade therefore entered the kitchen through small but high-impact commodities whose weight was modest relative to value. Jyotirisvara's discussion of betel, areca and aromatics in medieval Mithila illustrates this wider circulation. The presence of non-local flavouring agents

reveals market integration, but historians should distinguish a named imported ingredient from evidence that it was common in every household.

From landscape to meal: a social chain

Figure 182 — From landscape to meal: a social chain

46.19 Flattened and parched rice: when a grain becomes a named food

The Varna-ratnakara is particularly important because it moves the evidence from generic rice cultivation to named forms of processed rice. Jyotirisvara mentions chura or flattened/parched rice and farhi or fried/parched rice among a wider culinary vocabulary. Such foods are technically significant because processing changes portability, shelf life, texture and the amount of cooking required at the point of consumption. They are also socially significant because processed grain can serve travellers, guests and feast settings differently from freshly boiled rice. This is firmer evidence for medieval Mithila food history than any attempt to infer an identical dish directly from prehistoric rice remains.

46.20 Chura with curd: a medieval textual anchor and a continuity question

One of the most striking passages associated with Jyotirisvara describes fine chura served with abundant curd and cream. The combination is recognisable in later Mithila food culture, making it tempting to speak of unbroken continuity. The safer conclusion is more precise: the text anchors a rice-and-curd combination in early-fourteenth-century Mithila, while later evidence documents its persistence and elaboration. Continuity across the centuries is plausible where intervening evidence exists, but the medieval text should not be stretched backward into early historic Vajji or prehistoric north Bihar without proof.

46.21 Feast lists as social documents

Jyotirisvara's culinary lists include multiple prepared foods and sweets rather than a single subsistence meal. A feast list is therefore evidence of classification, abundance and social display. It may exaggerate variety for literary effect, but that very excess is historically informative: elite and ceremonial eating valued multiplicity, sequencing and the ability to mobilise specialised ingredients. Feast descriptions also illuminate servants, cooks, vessels, hospitality and status. They should not be treated as statistically representative of

peasant diets, yet they show what a medieval author expected readers or listeners to recognise as desirable food.

46.22 Betel after the meal: consumption beyond nutrition

Betel leaf, areca nut, lime and aromatics belong to food history even though they are not staple nourishment. Varna-ratnakara devotes attention to betel and its qualities, and references to paan as mouth-freshening or social consumption show how eating extended into etiquette, hospitality and bodily presentation. Because areca and some aromatics were traded over distance, the betel complex also connected Mithila to wider commercial circuits. Its social role reminds us that cuisine is not only calories: taste, fragrance, sociability and gift exchange are historical practices.

46.23 Food labour: growing is only the first stage

Every meal required invisible work after harvest: threshing, husking, pounding, grinding, winnowing, washing, churning, cutting, fermenting, cooking and cleaning. Much of this labour was organised within households and was frequently gendered, though the exact division varied by class, community and period. Large households, courts, monasteries and feast settings could employ specialised cooks and servants. Food history therefore belongs to labour history. The technologies of hand-pounding rice, grinding grain or churning curd determine daily time expenditure as surely as the crops themselves determine calories.

46.24 Storage, scarcity and the politics of the granary

Surplus mattered only if it could survive. Grain storage protected households against the gap between harvests, supported seed retention and allowed rulers, landlords, temples or monasteries to command reserves. Storage vessels, pits and granary-like facilities are therefore part of food history even when no meal remains. In flood-prone Mithila, storage location and protection from moisture were especially important. Control over stored grain could also create hierarchy: households with reserves were better able to survive crop failure, lend grain, feed dependants or sell into high-price markets.

46.25 Flood, drought and seasonal hunger

The same rivers that sustained rice, fish and transport could destroy fields and homes. Food history must therefore include bad years, not only feast descriptions. Flood, channel migration, drought, crop disease and political disruption could reduce harvests or interrupt markets. Households responded through crop diversity, stored grain, fishing, gathered foods, livestock sales, borrowing, migration and patronage networks. These strategies are difficult to recover evenly before the colonial period, but the ecological logic is durable and should frame interpretation of the region's agrarian resilience.

46.26 Anga, Champa and Vikramshila: provisioning an eastern corridor

Anga's position along the Ganga and routes toward Bengal made food supply part of a wider exchange economy. Urban Champa and, later, the great monastic establishment at Vikramshila required flows of grain, fuel, dairy, vegetables and other provisions from surrounding producers. Archaeology at Vikramshila demonstrates the scale of the residential institution, but not a secure item-by-item menu. The correct historical inference is therefore institutional demand: hundreds of resident or visiting consumers would have tied the monastery to villages, markets, donations and transport networks in the Bhagalpur-Anga zone.

46.27 Vegetarian and non-vegetarian histories cannot be reduced to a single regional rule

The sources document both plant-rich agricultural systems and the exploitation of animals and aquatic resources. Religious prescriptions, caste practices, household wealth, occupation and ecology created different food regimes. It is therefore misleading to describe ancient or medieval Mithila, Vajji and Anga as uniformly vegetarian or uniformly meat-eating. Archaeology records what some people consumed or deposited; normative texts record what authors prescribed; literary texts record what was imaginable or prestigious. Their overlap is historically meaningful, but none of them alone represents the entire population.

46.28 Regional cuisine identities are historical formations

Modern labels such as Maithil cuisine or Angika cuisine organise living repertoires of dishes, festival foods and tastes. They are important evidence for modern identity, but they should not be treated as fixed containers extending unchanged into antiquity. Some ingredients and techniques have deep histories; some named preparations are textually anchored in the medieval period; others may be early modern or modern innovations. Food identity is therefore layered. The historian's task is to date each layer wherever possible rather than choose between the equally misleading claims that everything is ancient or everything is recent.

Figure 183 — Chronology firewall for regional cuisine

46.29 Method: from ingredient to dish, and from dish to identity

A rigorous food history proceeds through several distinct questions. First, what plants and animals were available and used? Second, what processing and cooking techniques are materially visible? Third, when do texts begin to name particular foods or combinations? Fourth, how were meals distributed through households, markets, monasteries, courts and ritual events? Fifth, when do later communities begin to describe these practices as markers of a regional cuisine? Keeping these questions separate prevents both archaeological minimalism and culinary romanticism. It also allows genuine continuities—such as the medieval textual anchoring of chura and curd—to stand out more clearly because they are not buried beneath unsupported claims.

46.30 Conclusion: food as an archive of ecology, labour and memory

The food history of Mithila, Vajji and Anga is a history of adaptation to an alluvial world. Rice became central without eliminating winter cereals, pulses, oilseeds, fish, livestock, fruits and gathered resources. Towns and monasteries transformed surplus into markets, alms and institutional provisioning. Medieval Mithila's Varna-ratnakara provides a rare lexical window into processed rice, curd, cream, sweets, betel and feast culture, allowing some culinary practices to be dated with unusual confidence. Yet the strongest conclusion is methodological as much as culinary: modern cuisine preserves real historical memory, but that memory must be tested against dated evidence. When archaeology, text and later practice converge, the region's food traditions become not a timeless menu but a layered record of ecology, labour, exchange, ritual and identity.

Table 46.1 — Evidence domains for the food history of Mithila, Vajji and Anga

Evidence domain	What it can establish	Principal limit
Archaeobotanical remains	Cultivated and gathered plants; crop diversity; sometimes processing	Preservation and recovery are uneven; a grain does not identify a recipe
Faunal and aquatic remains	Animals, fish, shell and patterns of exploitation	Species presence does not automatically identify who ate it or under what rules
Hearths, ovens, querns and pottery	Processing, heat, storage and serving technologies	Function may be ambiguous; vessels rarely preserve named dishes
Early historic religious texts	Alms, hospitality, ethical rules and institutional eating	Normative or narrative sources are not population-wide menus
Varna-ratnakara	Early-fourteenth-century Mithila food names, feast vocabulary, chura-curd and betel culture	Literary abundance may over-represent elite or ceremonial consumption
Monastic and urban archaeology	Scale of collective provisioning and dependence on rural surplus	Architecture demonstrates demand more securely than a specific menu
Later ethnography and modern cuisine	Living techniques, identities and possible continuities	Cannot be projected backward without intervening evidence

Chapter 47 — Mithila Painting Before and Beyond the Modern Art Market

47.1 Why the pre-market history is difficult to write

Mithila painting presents a paradox for the social historian. The practice is repeatedly described as old, yet its most durable and datable corpus is overwhelmingly modern because the older media were intentionally temporary. Floor diagrams were renewed, mud-plastered walls were resurfaced, pigments faded, houses were rebuilt, and floods, earthquakes and poverty repeatedly altered domestic architecture. The result is a severe survival bias. A responsible history therefore cannot begin with the modern paper painting and simply project its forms backward. It must distinguish surviving objects, dated photographs, textual or ritual evidence, later recollection and present practice, and then ask where those independent lines of evidence genuinely converge.

47.2 Painting was embedded in domestic space before it became a portable object

Before the paper market, much of the documented painting tradition belonged to the house rather than to an autonomous object called a work of art. Images were made on earthen floors, plastered walls, thresholds, domestic shrines and the nuptial chamber. Their location mattered because the painted surface helped constitute a ritual setting. The same image moved to paper could preserve motifs and line habits while changing its social function: a wall participated in a wedding; a sheet could be stored, signed, priced, transported and exhibited. The historian must therefore treat surface, location and occasion as part of the work, not as detachable background.

Figure 184 — Evidence chronology: from domestic surface

Figure 184 — Evidence chronology: from domestic surface to portable art

47.3 Arian: temporary geometry and the problem of preservation

Arian designs are among the clearest examples of why material survival cannot be equated with historical importance. Made on floors with rice paste and, in some practices, additional colour, they marked auspicious and ritually activated spaces for vows, festivals, household worship and life-cycle ceremonies. Their very purpose often required renewal rather than permanent conservation. Consequently, the absence of an old arian object in a museum does not prove the absence of the practice, while a modern drawing of an arian does not by itself establish the age of every motif. The strongest method combines dated documentation of practice with careful comparison of recurring design grammars.

47.4 Kohbar painting and the nuptial chamber

The kohbar ghar, or nuptial chamber, became the best-known architectural setting for Mithila wall painting because marriage rituals concentrated painted imagery, women's ceremonial authority and fertility symbolism in one interior space. Lotus, bamboo, aquatic creatures, divine figures and auspicious signs could be combined in highly structured compositions. Yet the term kohbar should not be reduced to a market genre. Before portability, the image belonged to a sequence of wedding acts, songs, kin relations and controlled access to the room. Its historical meaning therefore includes who painted, who entered, who interpreted the motifs, and when the painting was renewed or covered.

47.5 The gosainghar and the wider domestic sacred environment

Painting also belonged to the gosainghar or household deity space and to other ritual surfaces inside the residential compound. This wider distribution matters because it prevents the history of Mithila painting from being reduced to marriage alone. Domestic visual culture linked lineage deities, calendrical worship, women's ritual work and the material maintenance of the home. It also blurred categories that museums later separated into painting, drawing, floor art and decoration. For historical reconstruction, a wall image in a shrine and a paper sheet bearing similar motifs are related, but they are not functionally identical. The transfer from place-bound efficacy to portable display is itself a historical event.

Domestic ritual painting as a spatial system

Analytical schematic, not a reconstruction of one excavated or universally standard house plan.

Figure 185 — Domestic ritual painting as a spatial system

47.6 Materials: mud plaster, rice paste, soot, vegetal colour and the archive that vanished

The older domestic media encouraged loss. Earthen walls required replastering; rice paste was vulnerable to abrasion, insects and water; soot, mineral and vegetal colours weathered differently; roofs and walls were periodically rebuilt. These materials make the household a recurring workshop in which restoration and re-creation were normal. Permanence was not necessarily the aim. This helps explain why the twentieth-century paper archive is so much denser than the earlier material record. It also cautions against equating the start of collecting with the start of painting. What becomes historically visible at a particular moment may reflect a change in medium, documentation or institutional attention rather than a sudden cultural invention.

47.7 Women's collective labour was also skilled artistic labour

Early observers often described household painting as ordinary women's work. That formulation risks hiding expertise inside domestic routine. William Archer's own account, despite his restrictive conclusions, recorded cooperative work in which experienced women directed composition while younger women learned by watching and assisting. Painting therefore involved differentiated skill, memory, judgement and pedagogy. The fact that it occurred within marriage preparation or household ritual does not make it aesthetically automatic. Social history should recover the collective conditions of production without erasing individual ability. The later appearance of named professional artists did not create skill from nothing; it changed the institutions through which skill was recognized.

47.8 Apprenticeship without an academy

The domestic transmission of painting knowledge did not require a formal art school. Girls and younger women could learn by preparing surfaces and tools, observing senior painters, repeating motifs, assisting with colour and participating in ritual occasions. Such apprenticeship was episodic, kin-based and embodied. It transmitted not only visual forms but also knowledge of when a design was appropriate, which part of the house it belonged to, what ritual sequence surrounded it and which songs or narratives accompanied the occasion. Once painting moved onto paper and into training centres, instruction could become more regular and explicit. The contrast reveals institutional change without implying that pre-market learning was unsystematic.

47.9 Caste idioms are evidence, not prisons

Twentieth-century descriptions often sorted Mithila painting into caste-linked styles, especially contrasting colour-filled Brahmin paintings with line-dominant Kayastha work. Such patterns are historically useful because social networks, marriage circles and women's household training could reinforce shared conventions. But caste labels become misleading when treated as rigid aesthetic laws. Archer's photographs already show individual variation within the categories he emphasized. Later artists crossed, combined and transformed stylistic conventions. A social history should therefore ask how caste organized access, patronage, seclusion, labour time and recognition, while leaving room for household difference, individual experimentation and historical change.

47.10 Lower-caste painting and the archive of omission

The early English-language archive disproportionately documented upper-caste households. Archer acknowledged that other communities painted, yet his published selection concentrated on Brahmin and Kayastha work. That imbalance shaped later definitions of what counted as authentic Mithila painting.

When Dalit and other non-elite artists entered the paper market more visibly, their subjects and techniques were sometimes treated as deviations rather than as evidence that the earlier archive had been socially selective. The historian must therefore read absence critically. A sparse record of a community's painting may reflect unequal access to photographers, collectors, patrons and institutions, not the absence of visual practice.

47.11 Individual invention existed inside ritual repertoires

Ritual repetition does not eliminate invention. A painter can work within an inherited vocabulary while varying scale, placement, rhythm, humour, density and narrative detail. This point matters because older classifications of "folk" or "ritual" art often treated individual authorship as irrelevant or even impossible. Yet historical photographs show differences between painters working in similar social contexts. Later named artists make the pattern clearer, but they should not be used to imagine that individuality began only with the art market. The stronger conclusion is that portability, signatures, exhibitions and sales made individual authorship easier for institutions to see, record and reward.

47.12 Secular motifs were present before the paper market

The pre-market domestic repertoire was not confined to timeless sacred symbols. Among the photographs discussed from Archer's late-1930s and early-1940s documentation is a nuptial-chamber wall that included a railway scene above religious imagery. The example is historically important because it demonstrates that painters could incorporate technologies and experiences of contemporary life before commercialization on paper. Ritual context and observation of modernity were therefore not mutually exclusive. This weakens any model in which the 1960s market suddenly introduced creativity or secular subject matter. What the market changed most dramatically was portability, audience, economic value and the range of incentives for sustained narrative experimentation.

47.13 The 1934 Bihar-Nepal earthquake and an accidental colonial encounter

William G. Archer first encountered Mithila wall paintings while inspecting earthquake damage in 1934. Broken and fallen outer walls exposed interior painted surfaces that were normally embedded in private domestic space. The event is a reminder that discovery is a category of the observer, not the origin of the practice. The paintings were not discovered by the households that made and used them; they became newly visible to a colonial official whose administrative duties gave him access after a disaster. The earthquake therefore belongs to the history of documentation and external reception, not to the beginning of Mithila painting itself.

47.14 The photographic archive of 1938–1940

Archer did not create a substantial photographic record during the immediate earthquake relief. Later, while travelling widely in Bihar, he photographed more than 150 painted walls in Mithila between 1938 and 1940. Those images are among the most important near-direct records of domestic painting before the paper market. They preserve compositions that the physical walls could not preserve and allow later scholars to test claims about continuity and change. At the same time, the archive is selective: access depended on caste, household permission, gender segregation, route and the observer's own interests. Photographs are therefore invaluable evidence, but not a neutral census of all painting in Mithila.

47.15 Archer's 1949 "Maithil Painting" and the power to classify

Archer's article "Maithil Painting," published in *Marg* in 1949, introduced the paintings to a much wider English-language art public. He treated them as ritual art and strongly emphasized caste-based stylistic categories. His praise of their visual power coexisted with assumptions that ritual repetition and women's domestic lives restricted creativity. That contradiction became influential because classification determines what later viewers expect to find. Once Mithila painting was framed as a stable caste-bound ritual tradition, individual variation, lower-caste work and secular imagery could appear secondary. Chapter 47 therefore treats Archer both as a crucial recorder and as a historically situated interpreter whose categories require scrutiny.

47.16 What the early colonial archive could not hear

The problem was not only what Archer photographed but whose explanations he could obtain. Upper-caste women often lived under forms of seclusion that limited direct interaction with an unrelated European male official. Men could provide names of household heads, dates and broad identifications, but they did not necessarily possess women's detailed ritual knowledge of the nuptial chamber. Later ethnography has shown that women's ceremonial worlds were partly autonomous within the household. This means that the visual archive and the interpretive archive are unevenly matched. A rigorous history must therefore distinguish what the photograph shows from what male intermediaries reported and from meanings later documented among women practitioners themselves.

47.17 Post-Independence fragility before commercialization

By the 1950s, visitors seeking the spectacular wall paintings described by Archer sometimes found fewer painted surfaces than expected. Poverty, changing domestic interiors, printed calendars and other visual media altered the household environment. This apparent decline should not be converted into a simple story of disappearance, because ritual practices could persist unevenly and older painted walls were never meant to survive indefinitely. Still, the evidence indicates that the tradition faced material pressure before the paper programme. The later shift to paper was therefore not merely an art-market innovation; it emerged at a moment when economic crisis, changing houses and state handicraft policy were already reshaping the conditions of domestic painting.

47.18 The drought of the mid-1960s created a new economic context

A severe drought and food crisis in north Bihar during the mid-1960s formed the immediate background to the government-supported attempt to turn painting into supplementary income. The initiative is historically important because it linked disaster relief, development policy, women's labour and cultural preservation. It did not invent the iconography, but it altered the material support and economic purpose of painting. The same woman could now transform knowledge learned for a wall or ritual floor into a portable sheet with a buyer elsewhere. That shift created new possibilities, but it also exposed artists to selection by officials, dealers, tourists and institutions whose preferences could influence what was produced and valued.

47.19 Bhaskar Kulkarni, Pupul Jayakar and the paper experiment

Pupul Jayakar, working within India's handicrafts-development institutions, encouraged an intervention in which the artist Bhaskar Kulkarni brought handmade paper to Madhubani and asked women known for wall painting to experiment with portable work. By 1967–1968, paper paintings were being produced and sold through handicraft channels. This episode should be understood as a medium transition, not as the birth

of Mithila painting. The imagery, line discipline and ritual knowledge preceded the intervention; paper altered durability, scale, transport, pricing and the possibility of repeated production for strangers. Chapter 48 examines the twentieth-century cultural economy in greater detail; here the episode marks the boundary between domestic surface and portable object.

47.20 A change of medium changes the social life of the image

When a painted image leaves the wall for paper, several things happen at once. It becomes durable enough to archive, light enough to transport, discrete enough to count and price, and flat enough to display in exhibitions or private collections. The work can acquire a signature and provenance independent of the house in which its motifs were learned. At the same time, ritual efficacy may become optional rather than central: a kohbar motif can be painted without a wedding taking place. This does not mean that paper destroys tradition. It means that the image acquires additional lives—commodity, artwork, document, gift, political statement and family income source—alongside ritual continuity.

Portability changes the social life of an image

	Wall / floor	Paper	Gallery / museum / new media
Duration	temporary / renewed	storable / sellable	collectable / reproducible
Authorship	often collective or unnamed	increasingly named	individual careers foregrounded
Audience	household / ritual participants	buyers and wider publics	institutions, critics, transnational viewers
Subject range	ritual + domestic + occasional secular	ritual motifs + narrative expansion	autobiography, politics, ecology, memory
Value regime	auspicious efficacy / social obligation	income + recognition	art market + archive + cultural politics

Figure 186 — What changes when a ritual image becomes portable?

47.21 Naming the artist changes the archive

The paper market made it much easier to attach a woman's name to a specific object. That shift transformed art history. Named careers could be followed, compared and exhibited; innovation could be attributed to individuals; awards and commissions could create public reputations. Yet this new visibility can distort the past if historians assume that unnamed domestic work lacked authorship. Collective or household production followed a different social logic of attribution. The rise of named artists therefore reveals a transformation in the archive as much as in artistic practice. It also allows the historian to recover life histories that were largely unavailable in the male-mediated documentation of the 1930s and 1940s.

47.22 Paper opened narrative space as well as economic space

Portable painting encouraged artists to extend established visual languages into new narrative sequences. Religious stories remained important, but artists increasingly depicted autobiography, migration, illness,

social conflict, environmental concerns, village change and national or global events. This expansion should not be described as a simple movement from tradition to modernity. Secular observation already existed in older wall painting, while ritual subjects remained alive after commercialization. What changed was the capacity to make extended, collectible series for audiences beyond the household. Artists could use the visual authority of inherited motifs while reorganizing them to address experiences that the ritual wall had not been expected to record at length.

47.23 Income, household power and the limits of empowerment

The market created real income opportunities, especially for women in a region with limited access to paid employment, but economic agency was uneven. Earnings could increase a painter's status and bargaining power while still being controlled or appropriated within the household. Access to buyers, paper, training, travel and institutions also varied sharply. A history that celebrates empowerment without examining these mediations repeats the development rhetoric of the market itself. Conversely, describing commercialization only as exploitation ignores the ways artists used new income and public reputation. The relevant question is not whether the market liberated or corrupted the tradition, but how benefits and constraints were distributed by gender, caste, class and institutional access.

47.24 Dalit and non-elite artists changed the visual field

As paper painting spread beyond the initially favoured upper-caste households, Dalit and other non-elite artists brought subjects, line habits and social experiences that had been underrepresented in the earlier archive. Some works foregrounded labour, local heroes, community ritual and histories of discrimination. Their participation demonstrates why "Mithila painting" cannot be reduced to a single ritual style or social group. It also exposes the long shadow of early classification: institutions that had learned to equate authenticity with Brahmin and Kayastha conventions could undervalue painters whose work expanded the field. The history of style is therefore inseparable from the politics of recognition.

47.25 Mithila in Nepal: a connected but not identical history

The cultural region of Mithila crosses the India–Nepal border, and related ritual painting practices are found in the eastern and central Terai, especially around Janakpur. Marriage networks, pilgrimage, language and shared ritual repertoires connect the two sides, but institutional histories differ. Nepal-based women's organisations and development projects created their own pathways from domestic painting to commercial and public art. It is therefore more accurate to speak of connected histories than of a single uniform market trajectory. Cross-border comparison is valuable precisely because similar visual traditions responded differently to state institutions, tourism, urbanisation, women's organisations and local economies.

47.26 Beyond the "folk art" versus "modern art" binary

Mithila painting has repeatedly been classified as folk art, ritual art, handicraft, popular painting, tourist art or contemporary art. Each label highlights something but can also restrict what viewers are prepared to see. A ritual image can be formally inventive; a commercially produced paper can carry serious political argument; a painter without academy training can develop an individual oeuvre; and a museum object can remain tied to domestic memory. Recent scholarship therefore challenges the rigid opposition between anonymous tradition and individual modern art. The historical task is to trace the institutions that produced these categories and the consequences they had for price, prestige, collecting, criticism and the artists' own self-understanding.

47.27 Museum preservation solves one problem and creates another

Portable painting solved the problem of ephemerality by making works collectable, but museum preservation can detach images from the ritual spaces that once structured their use. A sheet can retain a kohbar motif while losing the room, songs, marriage sequence and collective labour that gave the motif one layer of meaning. Conversely, the museum can preserve an artist's name, date, pigments and provenance far better than a mud wall ever could. The correct response is not to reject collecting but to preserve context with the object. Photographs, oral histories, architectural description and documentation of use allow museums and archives to record both the image and the social world from which it emerged.

47.28 Painting became an archive of social and political experience

Once painters could produce portable series over many years, Mithila painting became a medium of historical narration in its own right. Artists depicted personal illness, journeys, violence, ecological campaigns, political events and changing gender relations. These works are not transparent photographs of society, but they are first-person visual arguments made by people whose voices were often poorly represented in administrative archives. Their value lies precisely in the combination of inherited visual language and contemporary testimony. The shift also demonstrates why the phrase “beyond the modern art market” matters: market circulation enabled visibility, but the paintings cannot be reduced to commodities because they became repositories of memory, critique and self-representation.

Evidence firewall for Mithila painting history

Figure 187 — Evidence firewall for the history of Mithila painting

47.29 Chronology firewall and method: read images together with institutions

The first error is to claim that every modern motif or stylistic label is ancient because the tradition itself is old. The second is to treat the 1934 photographs or the 1960s paper programme as the beginning of Mithila painting because that is when the archive becomes dense. Both positions confuse visibility with origin. The safer chronology distinguishes documented domestic ritual practice, colonial photographic recording, post-Independence handicraft intervention, individual artistic careers and contemporary institutional life. Continuity is strongest where independently dated evidence links these stages; where a gap remains, the

chapter states the gap rather than filling it with an origin legend. A social history of Mithila painting cannot be written from iconography alone. The same lotus or bamboo motif can function differently on a nuptial wall, on a sheet commissioned by a handicraft official, in a museum collection or in a contemporary political narrative. Historical meaning therefore requires attention to medium, maker, patron, location, audience, price, ritual occasion and mode of preservation. Photographs and paintings should be read beside household ethnography, institutional records, artist biographies and market history. This method protects the visual object from being treated either as a timeless ethnographic specimen or as an autonomous aesthetic form without social context.

47.30 Conclusion: continuity survives through transformation

Mithila painting did not move in a straight line from ancient ritual to modern commodity. Its history is better understood as a series of overlapping transformations. Domestic wall and floor practices created repertoires of image, skill and ritual authority; colonial photography made a selective portion visible; post-Independence development policy made the image portable and economically productive; named artists expanded subject matter and public voice; museums and global circulation created new archives and new hierarchies. Across these changes, continuity was neither rigid nor fictitious. It survived because artists repeatedly reworked inherited forms for new surfaces, audiences and purposes. Chapter 48 takes up the cultural economy that grew from this transformation in greater detail.

Table 47.1 — Evidence domains for the history of Mithila painting

Evidence domain	What it can establish	Main limitation
Surviving wall/floor practice	Ritual location, technique, contemporary use, spatial relationships	Most examples are recent; surfaces are repeatedly renewed
1938–1940 Archer photographs	Pre-paper compositions, household locations, selected caste/household contexts	Selective access; women’s own explanations are incompletely recorded
Published classifications	How outsiders and institutions defined “ritual,” “folk,” caste style and art	Classification may reproduce observer bias and shape later collecting
Paper paintings and named oeuvres	Individual careers, subject expansion, signatures, portable chronology	Market incentives alter medium, scale, audience and value
Oral history and ethnography	Artist memory, ritual knowledge, gendered practice, pedagogy	Retrospective memory must be dated and cross-checked
Museum/market records	Provenance, exhibitions, prices, institutional recognition	Collection history can detach the image from domestic context

Chapter 48 — Mithila Painting and the Twentieth-Century Cultural Economy

48.1 The twentieth-century cultural economy is a second history, not the origin of the art

Mithila painting entered a new historical regime in the twentieth century. The domestic ritual practice discussed in Chapter 47 did not suddenly begin when administrators, craft officials, collectors or museums noticed it. What changed was the social life of the image. A painted wall or floor was tied to a house, ceremony and cycle of renewal; a sheet of paper could be counted, priced, signed, packed, retailed, exhibited, collected and archived. This chapter therefore studies cultural economy rather than origins. It asks how institutions, markets, biographies and new media changed who could paint, who could earn, what counted as a work, how artistic reputation was produced and how a regional women's practice came to circulate in national and international art worlds.

48.2 The 1934 earthquake created visibility through destruction

The Bihar–Nepal earthquake of 1934 is a crucial event in the modern archive because damaged houses exposed painted interior walls that were normally difficult for an outsider to see. W. G. Archer, then serving in the region, encountered the paintings during inspections connected with the disaster. The earthquake should not be narrated as the birth of Mithila painting. Its historical importance lies elsewhere: it disrupted domestic architecture and created an accidental window through which a colonial official could see and later document an art practice embedded in women's interior spaces. A cultural economy begins partly with such acts of visibility, because documentation can detach a practice from its local context and present it to new audiences who possess different categories of value.

48.3 Archer's photographs and 1949 article helped create a metropolitan art object

Archer's later photographs and his 1949 *Marg* article, "Maithil Painting," gave the wall paintings a durable place in English-language art writing. Reproduction in photographs and print did more than preserve motifs. It selected certain houses, social groups, images and interpretations for circulation. Metropolitan readers could now compare, classify and admire works without participating in the rituals that had produced them. Archer's categories—especially his emphasis on Brahmin and Kayastha styles and his interpretive interest in sexuality and tantric symbolism—were influential but not neutral. The twentieth-century cultural economy was therefore shaped from the beginning by a gatekeeping problem: the people who documented and published the art could affect which practitioners and meanings became visible to the wider world.

48.4 Independence changed the institutional setting of craft and rural art

After independence, the Indian state treated handicrafts and village industries as fields in which cultural preservation, employment and national identity could reinforce one another. This policy environment mattered for Mithila painting. Domestic art could now be approached not merely as ethnographic curiosity but as a potential source of rural income and as evidence of a distinctive regional heritage within the nation. Yet craft policy also brought administrative categories: objects needed to be portable, collectable, saleable and legible to buyers. The emerging cultural economy therefore linked welfare and aesthetics. Government-

supported institutions could provide materials and market access while simultaneously encouraging artists to translate household practices into products that could move through exhibitions, emporia and urban retail networks.

Twentieth-century transformation

Method: dates mark changes in documentation, institutions and markets; they do not mark the "birth" of the older ritual practice.

Figure 188 — Twentieth-century transformation: from documentation to cultural economy

48.5 The drought of 1966–68 turned cultural policy into an economic intervention

Accounts of the modern paper-painting movement repeatedly place the severe north Bihar drought of the later 1960s at the centre of the transition. Crop failure and rural distress created urgency for supplementary employment. The All India Handicrafts Board and associated officials supported experiments in which women were encouraged to reproduce or adapt wall and floor imagery on handmade paper. The purpose was practical as well as cultural: paper painting could generate cash without requiring women to leave the household for wage labour elsewhere. The intervention should not be romanticised. Drought made the experiment possible partly because economic vulnerability made new income sources necessary. Cultural entrepreneurship thus emerged from the intersection of artistic knowledge, state policy and agrarian crisis.

48.6 Pupul Jayakar, Bhaskar Kulkarni and the institutional memory of the “paper experiment”

Later accounts commonly associate the government-supported transition with Pupul Jayakar's handicrafts-development network and with Bhaskar Kulkarni, who worked with artists in the Madhubani area and encouraged painting on paper. The details of institutional responsibility vary across recollections, so the safest historical formulation is to treat the change as a coordinated state-and-intermediary experiment rather than the invention of a single individual. The crucial shift was material and economic: handmade sheets, pigments suited to portable work, collection arrangements and access to external buyers created a chain that did not previously exist at the same scale. The intervention did not simply transfer motifs; it created a new infrastructure in which a household skill could become a commodity and an artist could become a named producer.

48.7 Paper was not a neutral support: it was an economic technology

Changing the surface from wall to paper altered size, durability, transport and ownership. A wall painting belonged to a building and could disappear when plaster was renewed. A paper work could be folded or rolled, moved to Delhi, stored in a warehouse, sold in an emporium, carried abroad and later accessioned by a museum. This portability converted ephemeral labour into an object that could accumulate provenance and price. Paper also encouraged standard dimensions and repeatable production schedules, making batches easier to purchase and distribute. At the same time, it liberated painters from the architectural limits of the kohbar room. New themes, narrative series and individual experiments could now exist independently of a specific wedding or household shrine.

48.8 Price made labour visible but also measurable in new ways

Once paintings entered markets, labour acquired a monetary form. Time spent drawing, filling colour, preparing paper and repeating borders could be compared with the price offered by an intermediary or buyer. This could make women's skilled work newly visible inside the household, particularly where cash income had previously depended mainly on male-controlled agriculture or migration. Yet price could also simplify artistic labour. Buyers could favour particular sizes, dense compositions or recognisable motifs because they sold well. A cultural economy therefore introduced a new negotiation between ritual competence, aesthetic ambition and market demand. The same transformation that enabled income also created incentives to accelerate production, repeat successful subjects and tailor works to external expectations.

48.9 Signatures and biographies created the modern category of the "Mithila artist"

The portable work made individual authorship easier to record. A wall painting might be remembered locally as the work of women from a household or kin group; a sheet could carry a name, be bought directly from a painter, appear in a catalogue and later be linked to other works by the same hand. Biographies then became part of value. Buyers and museums wanted to know who had painted a work, where she lived, which social group she came from and how her style differed from others. This process helped produce internationally recognised careers, but it also changed the archive by privileging painters whose names and works entered collecting circuits. Unknown or locally valued practitioners could remain invisible even when their artistic labour was equally skilled.

The portable-painting value chain

Money, reputation and information can travel back toward the painter, but not evenly. Intermediaries can widen access while also controlling selection, price and visibility.

Figure 189 — The portable-painting value chain

48.10 Jagdamba Devi and Sita Devi demonstrate how state recognition changed artistic status

The rise of named careers can be traced through public honours. Jagdamba Devi of Madhubani was awarded the Padma Shri in 1975, and Sita Devi, identified in the 1981 Gazette as a painter from Madhubani, also received the Padma Shri. Such honours mattered beyond personal prestige. They signalled that an activity previously associated with women's household ritual could be recognised by the state as nationally significant art. Awards affected cultural economy by increasing visibility, attracting visitors and buyers, and helping distinguish particular artists from a wider field of producers. At the same time, award systems inevitably select a small number of representatives. The fame of a few artists should therefore be read as evidence of institutional legitimization, not as a complete measure of artistic importance within Mithila.

48.11 Ganga Devi shows how the paper medium supported autobiography

Ganga Devi became one of the most important examples of an artist whose portable work expanded beyond ritual subjects into sustained personal narrative. Her paintings retained the disciplined line, pattern and visual vocabulary associated with Mithila while accommodating journeys, public events and episodes from her own life. Accounts of her work on illness and medical treatment are especially important because they demonstrate that a form often marketed as “traditional” could become autobiographical without ceasing to be recognisably Mithila painting. The economic market and the artistic archive intersected here: a durable series could be collected, published and studied as the work of an individual over time. Modernity entered not by erasing tradition but by allowing inherited visual language to narrate new experience.

48.12 Mahasundari Devi, Godawari Dutta and other recognised painters widened the field of authorship

The twentieth-century art world did not produce a single representative woman artist. Painters including Mahasundari Devi, Godawari Dutta, Baua Devi and others developed identifiable bodies of work, taught younger artists and participated in exhibitions and public institutions. Their careers reveal how the cultural

economy multiplied forms of expertise. A painter could be a ritual specialist, wage earner, teacher, exhibitor and cultural representative at the same time. The growth of named careers also complicated the old idea that “folk art” was anonymous and collectively repeated. Individuality had existed within domestic traditions, but the modern market made it easier to document stylistic choice, long-term experimentation and the relation between biography and subject matter.

48.13 “Caste styles” became both descriptive shorthand and market packaging

Early scholarship and the first market frequently classified paintings as Brahmin, Kayastha or, later, Dalit styles. These labels corresponded to some real differences in domestic practice, preferred motifs, line treatment, colour and social access. Yet the market could harden flexible tendencies into fixed brands. A buyer might expect dense colour from one category and fine line from another, encouraging artists to perform an identity that matched metropolitan expectations. Later scholarship has challenged the assumption that artistic practice was ever confined to only two upper-caste groups. The cultural economy must therefore be analysed as a field in which social classification could be reproduced, contested and commercialised. Style labels are historical evidence, but they are not timeless rules governing every painter.

48.14 Dalit participation changed both the market and the story of Mithila painting

By the later twentieth century, artists from Dalit communities became increasingly visible in portable painting. Godna-inspired line systems, local deities, Raja Salhesh traditions, labouring life and other subjects entered markets that had initially foregrounded Brahmin and Kayastha women. This expansion was economically important because it widened access to painting income, but it was also historiographically important. It exposed the narrowness of an archive that had equated “Mithila painting” with upper-caste ritual art. The work of artists such as Jamuna Devi, and later the nationally recognised Shanti Devi and Shivan Paswan, demonstrates that innovation could arise from artists who were previously marginal to the institutions that selected and marketed the art.

48.15 Local collection centres linked village production to distant buyers

The market required institutions between the painter and the final purchaser. British Museum records for paintings made in Madhubani between 1965 and 1972 include works associated with the Alok Hastkala Kendra, while acquisition notes for other examples record purchase through the Bihar State Emporium in Delhi. Such documentation reveals a chain: paintings could be produced in villages, gathered locally, moved through state-linked retail infrastructure and then acquired by urban or foreign buyers. These centres solved practical problems of transport and market access, but they also exercised selection. Which paintings were collected, which artists were represented, and what price was paid were decisions with long-term consequences for reputation and income.

48.16 The Bihar State Emporium converted regional art into a reproducible retail category

An emporium does more than sell objects. It organises them by region, craft and price, presenting the nation as a collection of recognisable cultural products. Mithila paintings in the Bihar State Emporium could therefore be encountered by buyers who had never visited Madhubani or participated in Maithil ritual life. Retail transformed context: a kohbar-derived image could hang beside textiles, metalwork or other state-labelled crafts. This widened demand and helped stabilise “Madhubani painting” as a category familiar to

Indian urban consumers. Yet emporium presentation could also flatten differences among villages, artists and ritual contexts. The cultural economy gained scale partly by simplifying the story told about what was being sold.

48.17 National awards transformed household painters into public cultural figures

Government awards, craft competitions and invitations to demonstrate painting created public careers that had no exact equivalent in the older domestic system. Recognition could bring cash prizes, commissions, travel and a stronger bargaining position with buyers. It could also make an artist into a symbolic representative of Bihar or of Indian folk art. The award system thus converted artistic distinction into institutional capital. Because recognition was scarce, however, it could produce hierarchy among painters. A handful of award-winning names might command attention while many others remained suppliers in a low-price craft market. The historian should therefore read awards both as evidence of achievement and as mechanisms through which states help construct artistic canons.

48.18 Museums turned commodities into heritage and art-historical evidence

When a painting enters a museum, its economic life does not end; its symbolic value changes. Accession numbers, dates, artist names, materials and provenance become durable metadata. British Museum holdings from the late 1960s and early 1970s preserve handmade-paper works and record how some reached Delhi emporia or local centres before entering collections. Museums can protect works from dispersal and make individual careers studyable, but selection creates another filter. Objects that museums acquire may be treated as representative long after the market conditions that produced them have changed. Museum history is therefore part of the cultural economy: institutional preservation shapes what future scholars are able to know.

Figure 190 — How cultural value was produced

Figure 190 — How cultural value was produced

48.19 The 1970s created a transnational field of collectors, exhibitions and publications

Recent scholarship describes the 1970s as a decisive phase in the globalization of Mithila painting. Western interest in Indian spirituality, craft and countercultural aesthetics created audiences beyond the government emporium. Paintings travelled through collectors, scholars, museums and exhibitions, while books reproduced works for readers who might never see the originals. Transnational circulation increased prices and prestige for some artists and encouraged new subjects tailored to wider audiences. It also created interpretive risks: foreign viewers could reduce complex domestic imagery to exotic sexuality, tantric symbolism or timeless village spirituality. International success therefore expanded the cultural economy while increasing the importance of contextual scholarship.

48.20 Exhibitions changed how paintings were compared and judged

A ritual wall is encountered in a house; an exhibition places many portable works side by side under labels. This arrangement invites comparison among artists, styles, social groups and periods. The 1978 exhibition of Mithila paintings organised by Raymond Owens at the University of Texas, discussed in recent scholarship, is an example of how the art entered museum-style presentation in the United States. Exhibitions could give artists visibility and provide cultural context, but curatorial decisions also framed interpretation. Titles, wall texts and selection could reinforce the categories of “folk,” “women’s art,” “ritual,” or “contemporary.” The cultural economy therefore included not only sale but the production of meaning in exhibition space.

48.21 The “folk art” label opened markets while limiting artistic mobility

Classification as folk or handicraft helped Mithila painting enter state craft programmes, emporia and specialist collections. Yet those same labels could restrict how works were evaluated. A painting by a named artist might be admired for authenticity or ethnographic value rather than composition, intellectual argument or personal experimentation. When an artist changed subject matter, critics could accuse her of losing tradition even though modern painters in other categories were expected to innovate. This asymmetry is central to the cultural economy. Market success depended partly on appearing recognisably traditional, while individual careers often depended on extending the tradition. Painters therefore negotiated a narrow space between recognisability and invention.

48.22 Income could alter household bargaining without eliminating gender inequality

Cash earnings from painting gave some women resources that were visibly linked to their own skill. Income could help meet food costs, schooling, medical expenses, dowry obligations or house construction and could strengthen a painter’s standing within the family. Yet earning money did not automatically transfer full control over that money. Male relatives could negotiate with buyers, travel to markets or manage bank accounts; domestic labour still had to be performed; and access to paper, training and contacts remained uneven. The strongest historical claim is therefore not that commercialization “liberated” Maithil women, but that it created a new economic resource whose effects depended on household structure, caste, class, age and access to institutions.

48.23 Commercialization could widen agency and narrow artistic choices at the same time

Artists gained new opportunities because buyers wanted paintings, but the market communicated preferences back to the village. Certain deities, wedding images, fish, peacocks, trees and dense decorative borders became instantly recognisable as “Madhubani.” Repetition could provide dependable income, yet it could also encourage standardisation. Some observers criticised buyer-driven production for weakening ritual knowledge or colour practices. Such criticism should itself be historicised: tradition was never motionless, and market demand did not erase artists’ intelligence. The key analytical point is that commercialization introduced a new source of constraint alongside older ritual, familial and caste expectations. Modern painters worked within several systems of obligation at once.

48.24 Men entered a field long represented as women’s art

The paper market created incentives for men to paint, organise production, teach or mediate sales. This shift unsettled the popular image of Mithila painting as exclusively women’s creativity. Male participation should not be treated simply as decline, because men could develop significant artistic careers and contribute to new themes. It did, however, alter labour competition and the gendered meaning of the practice. A household art that women had transmitted as part of ritual competence could become an income-producing occupation attractive to anyone with access to training and buyers. The twentieth-century cultural economy therefore changed not only the medium and market but the gender composition of the artistic field.

48.25 New subjects converted painting into a record of contemporary life

Portable works made it possible to paint events that had no fixed place in the older ritual repertoire. Artists depicted village disputes, travel, medical treatment, environmental campaigns, political themes and changing gender relations. A 1977 murder near Harinagar was later recorded in a substantial series of drawings by Krishnanand Jha, while Ganga Devi used painting to narrate personal experience. These works demonstrate that Mithila painting became a historical medium, not merely a decorative survival. The ability to preserve and sell narrative series encouraged painters to treat contemporary experience as worthy of visual record. Cultural economy and social history thus converged: the market created durable objects through which artists could document their own time.

48.26 Authenticity became a contested economic resource

As demand increased, claims of authenticity acquired monetary value. Buyers could prefer natural pigments, traditional motifs, particular villages or artists associated with established lineages. Dealers and institutions sometimes used caste, gender or ritual biography as markers of authenticity. Yet authenticity is not a simple survival from the past; it is also a modern argument about value. A paper painting made for sale can be deeply rooted in inherited practice, while a wall painting made for a tourist demonstration can itself be shaped by market expectation. The historian must therefore ask who invokes authenticity, for what audience and with what economic effect. Tradition became one of the currencies through which twentieth-century Mithila art was priced and legitimised.

48.27 The market produced new inequalities inside the painting economy

Not every painter benefited equally from rising demand. Artists with access to government officers, local centres, urban dealers, English-speaking scholars or international collectors could gain visibility that neighbours lacked. Awards and museum acquisitions could raise one career rapidly. Conversely, anonymous

production, low-price tourist work and subcontracted painting could remain poorly paid even while the art form's reputation grew. These inequalities caution against treating aggregate commercial success as proof of prosperity for all practitioners. The twentieth-century cultural economy had a star system at one end and routine craft labour at the other, with many intermediate forms of production. Understanding this range is essential to any social history of the art.

Opportunities and constraints

The market could widen agency and narrow choices at the same time. "Commercialization" is therefore a relationship to analyse, not a single verdict.

Figure 191 — Cultural economy: opportunities and constraints

48.28 Transnational recognition changed local aspirations

Foreign exhibitions and collectors did not operate only outside Mithila; news of international recognition returned to villages and affected how families imagined artistic careers. Travel, museum display and publication could transform a painter into a local model of success. Younger artists could learn that visual skill might produce income and mobility beyond agriculture or domestic labour. At the same time, external demand could reshape subject matter and scale. The cultural economy therefore functioned as a feedback loop: local practice supplied the market, the market created prestige, and prestige altered local decisions about who should learn to paint. This feedback helped turn a crisis-era employment experiment into a durable artistic sector.

48.29 Method: separate artistic change, market change and social change

Three different histories are often collapsed into one. Artistic change concerns line, colour, composition, subject and medium. Market change concerns price, portability, retail networks, buyers and institutions. Social change concerns gender, caste, household income, mobility and status. They interact, but none can be inferred automatically from another. A new pigment does not prove empowerment; an award does not prove high income; a high sale price does not prove that the artist received most of it. This chapter therefore treats the twentieth-century cultural economy as a network of relationships rather than a triumphalist story of "folk art becoming famous." Evidence must specify whether it concerns objects, institutions, money, reputation or lived social consequences.

48.30 Conclusion: the cultural economy made Mithila painting durable, mobile and politically legible

The twentieth century changed Mithila painting by creating infrastructures through which images, names and money could travel. Colonial documentation made selected domestic paintings visible; post-independence craft policy linked heritage with rural employment; the drought-era paper experiment created portable commodities; emporia and local centres distributed them; awards, museums and exhibitions produced prestige; and transnational collectors expanded the field. These processes gave many artists new income and unprecedented authorship, while also generating stereotypes, inequalities and pressure to satisfy buyers. The most important transformation was therefore not a simple passage from tradition to market. It was the creation of a cultural economy in which ritual knowledge, individual creativity, social identity and institutional value became permanently entangled.

Table 48.1 — Evidence domains for the twentieth-century cultural economy of Mithila painting

Evidence domain	What it can establish	Principal limit
Archer photographs and 1949 article	Early external documentation, selected households, metropolitan framing	Selective archive shaped by colonial access and interpretation
Government/craft-policy accounts	Drought-era intervention, paper supply, employment rationale, institutional support	Later recollections may simplify who initiated specific steps
Emporium and museum provenance	Movement through local centres, Bihar State Emporium, collections and dates	Preserves market survivors, not the full range of production
Awards and official gazettes	Public recognition and national legitimization of named artists	Honours represent selective institutional recognition, not income data
Artist biographies and monographs	Individual careers, innovation, travel, illness, narrative series	Famous artists are better documented than ordinary producers
Village ethnography and oral testimony	Household income, gender, caste, training and intermediary relations	Often local and time-specific; cannot stand for all Mithila
Exhibition and transnational records	Foreign reception, curatorial framing, collector networks	External taste can overrepresent particular themes and styles

Chapter 49 — Music, Song and Performance

49.1 Performance history requires an event, a repertoire and a social setting

Music becomes historical evidence only when it is attached to a dateable setting: who performed, for whom, on what occasion, in what language, and through what medium. A song-text without a performance context is not the same thing as a sounded event; a living performance is not by itself proof that the same melody, instrumentation or social meaning existed centuries earlier. This chapter therefore treats music, song and performance as connected but separately testable histories across Mithila, Vajji and Anga.

49.2 Sound is unusually vulnerable evidence

Buildings, manuscripts and metal objects may survive for centuries; sound disappears as it is made. Before recording technologies, historians must work through notation, literary description, iconography, surviving instruments, ritual prescriptions, named repertoires and later oral transmission. Each medium preserves something different. A manuscript can preserve words or musical signs but not a singer's timbre; a sculpture can show an instrument but not the tune; an oral rendition can preserve a practice while also accumulating later changes.

49.3 Pan-Indian music theory is a framework, not a regional transcript

The Natya-sastra, Dattilam and later Sanskrit musicological traditions provide indispensable concepts for rhythm, melody, performance and aesthetic response, but they cannot be treated as direct descriptions of village practice in Mithila or Anga. Their value is comparative and conceptual. Regional history begins where a text, manuscript, inscription, named patron, repertoire or securely located performance connects those wider traditions to the eastern Gangetic world.

49.4 Nanyadeva provides rare early evidence linking Mithila to written musicology

A particularly important bridge appears around the early twelfth century in the work associated with King Nanyadeva. The Sarasvati-hrdyalankara or Bharata-bhasya tradition attributed to him preserves substantial musicological discussion, and D. R. Widdess has shown that the Panika song examples transmit melody and tala information of exceptional value for the history of early Indian music. This evidence demonstrates learned musical activity connected with the Karnata courtly sphere; it does not prove that all inhabitants of Mithila followed the same repertory or theory.

Figure 192 — Evidence ladder for music and performance history

Strong claims require evidence appropriate to the date and performance context

Live / recorded performance

Direct evidence for a documented performance, not automatically for its antiquity

Named collections and field recordings

Evidence for repertoire, singers, occasions and variants at the time of collection

Texts, notation and manuscripts

Evidence for musical concepts, song-texts and elite/learned practice; performance must still be inferred

Images, instruments and material traces

Evidence for objects, bodily practice and representation; sound itself is not preserved

Retrospective memory

Useful for continuity claims only when checked against earlier layers

Figure 192 — Evidence ladder for music and performance history

49.5 Simraongarh was a node of patronage, but court evidence must not swallow social history

The Karnata political centre at Simraongarh created conditions in which scholarship, ritual, court ceremony and musical expertise could meet. Courtly sponsorship matters because it supported specialists and textual production, yet a royal musicological work is evidence first for a learned milieu. The social history of music also has to recover household, agricultural, devotional, itinerant and festival performance that usually left thinner written traces.

49.6 Medieval literary vocabulary records a world in which performance was socially visible

Jyotirisvara and later Maithili literary traditions contain descriptions of urban life, occupations, festive scenes, song and dramatic entertainment. Such texts show that performers and performance were recognizable components of social space. Their catalogues are literary constructions, however, and cannot be converted mechanically into census lists. The safest inference is that musical and theatrical labour formed part of the visible economy of courts, towns, ritual gatherings and public entertainment.

49.7 The project separates Mahakavi Vidyapati's Padavali from the later Vidyapati Thakkura

This volume follows its adopted two-Vidyapati framework. The core Maithili Padavali song tradition is assigned here to Mahakavi Vidyapati, placed before Jyotirisvara, while the later Vidyapati Thakkura belongs to the Oiniwar-associated Sanskrit and Avahatta documentary and courtly world. Because most modern scholarship instead combines these corpora under one fifteenth-century author, every use of conventional Vidyapati scholarship in this chapter is treated as evidence for reception, manuscripts and performance history rather than as a concession on authorship chronology.

49.8 A song tradition can outlive, reshape and even obscure authorship

Once lyrics circulate in performance, singers may shorten verses, alter wording, change melody, combine stanzas, attach a familiar bhanita, or adapt a song to a new ritual moment. The long afterlife of Vidyapati songs across Mithila and eastern India therefore has two historical dimensions: the earlier composition-history proposed by this project and the later, independently documentable history of circulation. Oral popularity is evidence for reception, not a secure method for assigning the date of composition.

49.9 Life-cycle songs organize music around social transition

Ethnographic classification of Maithili folksong repeatedly emphasizes birth, initiation, marriage and departure. These are not merely themes; they are timed social acts. The song announces who may speak, joke, bless, lament or instruct at a particular stage of a rite. Because different songs belong to different moments, the sequence of performance can reveal household hierarchy, gendered authority, kinship tension and the emotional management of transition more clearly than a decontextualized lyric collection.

Figure 193 — Song ecology across the social calendar

49.10 Marriage creates one of the densest performance sequences

Wedding repertoires stretch across preparation, auspicious opening, negotiations, ritual actions, teasing, the reception of the groom, departure and later return. IGNCA documentation notes the movement from Suhag songs toward Samdaun or farewell songs within a larger chain of named ritual genres. Historical analysis should therefore study wedding music as a sequence of performances rather than as a single genre, and should distinguish current documentation from claims that every named form is medieval in exactly its present shape.

49.11 Women are central custodians of much domestic repertoire

A large proportion of documented Maithili life-cycle singing is performed by women in spaces where formal literary archives historically recorded little. This makes women's performance a major archive of emotion, social commentary, ritual expertise and intergenerational instruction. It also creates a

methodological problem: twentieth- and twenty-first-century field documentation may preserve old structures, but the date of a song's present wording must be established separately from the antiquity of the rite.

49.12 Seasonal song turns the calendar into a musical structure

Barahmasa and related month-sequence traditions connect climate, separation, agricultural expectation and bodily feeling. Other songs cluster around monsoon, spring and named festivals. The important historical point is not that a single melody persisted unchanged, but that seasonal time repeatedly organized performance. In a floodplain and monsoon economy, the calendar was audible: rain, sowing, travel constraints, heat and absence became recurring frameworks through which social experience was sung.

49.13 Work songs join rhythm to labour without making labour picturesque

Songs associated with sowing, harvesting, winnowing, travel or other repetitive work can coordinate movement, relieve monotony, communicate practical knowledge and permit social commentary. The category should not be romanticized as proof of an undifferentiated village community. Work was divided by gender, age, occupation and property relations; therefore the right question is which workers sang, during which tasks, and whether performance expressed solidarity, instruction, complaint or hierarchy.

49.14 Devotional repertoires create overlapping sacred publics

Documented Maithili classifications include bhajan, kirtan, morning songs, family-deity songs, Bhagavati songs, Nachari and Maheshbani, among other forms. These labels show a dense relation between devotion and performance, but they also warn against treating "religious music" as one homogeneous field. Some performances are household-based, some congregational, some tied to pilgrimage or festival, and some shaped by professional or semi-professional performers.

49.15 Shaiva, Shakta and Vaishnava song traditions share a region without becoming identical

Mithila's sacred soundscape includes Shiva-Parvati narratives, goddess traditions, Krishna-centred lyric and family-deity repertoires. Shared melodies or performance spaces can encourage borrowing, while theological and ritual distinctions remain meaningful. The historical task is to trace movement among repertoires rather than assume either complete separation or complete syncretism. A genre name, deity and melody may each have a different history.

49.16 Muslim participation belongs inside the regional history of song

Regional documentation records Muslim Maithils participating in Maithili-language expressive culture, including forms associated with marriage and mourning. Such evidence is important because it prevents the musical history of Mithila from being reduced to one religious community. At the same time, the specific repertoire, social setting and date must be documented case by case; shared language does not erase differences in ritual obligation or devotional meaning.

49.17 Narrative song turns memory into performance

Katha-gatha traditions, heroic narratives and deity stories are performed rather than simply recited. Melody, repetition, gesture, dialogue and audience response determine how the story works socially. Salhesh, Lorik and related regional narratives therefore belong simultaneously to oral history, music and theatre. Their

present popularity can be documented securely; claims about the antiquity of particular episodes or melodies require earlier textual or material anchors.

49.18 Anga's Bihula-Bishahari complex joins song, ritual, theatre and image

In the Bhagalpur-Champanagar zone, the Bihula-Bishahari narrative is embedded in an annual ritual complex that includes songs, procession, worship, folk theatre and Manjusha objects or images. Modern documentation identifies the gatha and songs with the Angika-speaking region. The performance complex is historically valuable precisely because its media reinforce one another. Yet the date of the present festival form, the story's literary parallels and the antiquity of individual songs must remain separate questions.

Figure 194 — Three interacting performance circuits

49.19 Public performance creates temporary social space

A courtyard, shrine forecourt, village path, mela ground or urban stage becomes a different social environment while performance is underway. Audiences assemble, performers acquire temporary authority, donations circulate, traders benefit from crowds and local prestige is displayed. Music is therefore part of public culture and local economy as well as aesthetic expression. The same repertoire can change meaning when moved from a household rite to an amplified festival stage.

49.20 Instruments must be dated as carefully as songs

Historical references to drums, cymbals, strings or wind instruments should not be collapsed into the exact modern ensemble familiar from contemporary performances. Instrument names can shift, construction changes, and harmonium or electronic amplification belong to later technological histories. Iconography and texts can establish categories of sound production, while museum objects, photographs and recordings are needed to reconstruct specific modern instrument forms and combinations.

49.21 Rhythm links voice, body and collective coordination

Performance is not only melody and words. Clapping, percussion, walking, circular movement, dance steps and repeated refrains can coordinate bodies and signal transitions. Nanyadeva's notated material is especially valuable because it provides an early written window on relations between tala and melody, while later folk performance reveals other rhythmic systems through observation and recording. These bodies of evidence should be compared, not assumed to be identical.

49.22 Professional and semi-professional performers complicate the folk/classical divide

Regional performance has involved household singers, ritual specialists, mendicants, storytellers, theatre troupes, court musicians and later radio or stage artists. Their repertoires can cross the categories "folk," "devotional," "classical" and "popular." Those labels are often products of collectors, institutions and modern cultural policy. Social history should instead follow training, payment, patronage, mobility and audience.

49.23 India-Nepal circulation helped repertoires travel without fixing a single centre

Mithila's cultural geography crosses the modern India-Nepal border. Courts, pilgrimage, marriage, scholarship and migration connected the plains of north Bihar with the Tarai and Kathmandu Valley. Songs and dramatic forms could therefore move through people rather than through a single institutional channel. A repertoire documented in Nepal may preserve important evidence for Maithili circulation, but location of a surviving manuscript or performance does not automatically establish its place of composition.

49.24 Song and theatre meet at a porous boundary

Many performances alternate speech, lyric, gesture and instrumental accompaniment. Kirtaniya drama and other regional theatre traditions make the boundary between "song" and "play" especially porous. Chapter 50 examines dramatic cultures directly; the point here is methodological: a sung text may be part of a larger staged event, and extracting it as a poem can erase performer roles, entrances, audience interaction and musical timing.

49.25 Print created stable song collections while performance continued to vary

Printed anthologies made it easier to preserve, teach and circulate lyrics in standardized sequences. They also encouraged readers to imagine a definitive text where singers might know several variants. The growth of printed Vidyapati collections and Maithili song books therefore changed authority: editors, publishers and literary institutions increasingly shared with performers the power to decide what counted as an authentic song.

49.26 Recording, radio and amplification created a new performance history

The arrival of gramophone recording, radio, cassette, loudspeaker, film, television and digital media changed duration, voice production, audience size and circulation. A song that once depended on presence could become repeatable and commercially distributable. Amplification also reorganized festival soundscapes, allowing small ensembles to dominate large public spaces. These changes must be dated as modern transformations rather than projected into earlier performance practice.

49.27 Migration turns regional song into portable memory

Labour migration, education and urban settlement carry Maithili and Angika repertoires beyond the region. Songs performed in Delhi, Kolkata, Mumbai, the Gulf or diaspora communities can become markers of home, marriage network and language identity. Migration may preserve older pieces because they acquire nostalgic value, but it can also accelerate hybridization through new instruments, languages and performance formats.

Figure 195 — The Bihula-Bishahari performance complex in Anga

A ritual narrative can join song, theatre, procession, image and place without proving a single ancient origin date

Figure 195 — The Bihula-Bishahari performance complex in Anga

49.28 Festivals and cultural institutions can preserve and repackage at the same time

State festivals, academies, competitions, university departments and cultural organizations provide stages, honoraria and documentation that can sustain performers. They also select which genres represent the region publicly. A domestic women's song, a devotional narrative or an Angika folk drama may be shortened, costumed or amplified for the stage. Preservation therefore always has an institutional history and should not be mistaken for neutral transmission.

49.29 Method: separate composition, repertoire, performance and recording dates

Four dates may coexist in one song history. The underlying composition may be old; a named repertoire may be documented later; a particular performance may occur on a known date; and the surviving audio or video may be later still. Claims about continuity become stronger when several layers converge. When they do not, the historian should state the gap rather than fill it with cultural memory or modern popularity.

49.30 Conclusion: performance is a social infrastructure of memory

Across Mithila, Vajji and Anga, music links household transitions, seasonal time, labour, devotion, heroic narrative, festival assembly and public culture. Its history is neither a straight line from "ancient tradition" nor a sequence of isolated genres. It is a history of people repeatedly remaking repertoires in new settings. The

most durable continuity lies not in an unchanged melody but in the regional capacity to make social knowledge, emotion and collective memory audible through performance.

Table 49.1 — Evidence domains for reconstructing music, song and performance

Evidence domain	What it can establish	Principal limit
Musicological manuscripts and notation	Named concepts, melodic/rhythmic structures, learned practice, textual transmission	Usually strongest for elite/learned settings; does not reproduce actual historical sound
Literary song texts and anthologies	Lyrics, genre names, authorship claims, editorial canon and textual variants	Text may be separated from original melody, performer and occasion
Ritual and ethnographic documentation	Occasion, performers, sequence, social function, gendered and household practice	Date of observation is secure; antiquity of the observed form is a separate question
Iconography and surviving instruments	Instrument types, gesture, performance posture and material technologies	Representation may be symbolic; objects and names change over time
Audio, radio, film and video	Actual voice, tune, tempo, instrumentation, style and audience response at a known moment	Modern media can alter performance and cannot prove earlier sound without corroboration
Festival and institutional archives	Patronage, public staging, awards, programmes, repertoire selection and cultural policy	Institutions reshape what they document and present
Oral memory and performer testimony	Transmission routes, local attribution, learning histories and meanings given by performers	Memory is historically valuable but not a substitute for independent dating
Cross-regional comparison	Movement among Mithila, Anga, Bengal, Nepal and other eastern performance zones	Similarity alone does not establish origin, direction of borrowing or chronology

Chapter 50 — Theatre and Dramatic Cultures

50.1 Theatre is an event before it is a text

The history of theatre cannot be written from playbooks alone. A dramatic text preserves possible speech, songs, roles and sequences, but performance also requires bodies, voice, movement, music, costume, a place, an audience and a social occasion. For Mithila, Vajji and Anga the archive is therefore uneven: some periods preserve manuscripts but no witnessed staging; others preserve living performance with uncertain antiquity; still others leave only literary references to actors or entertainment. This chapter uses a layered method. A play may establish a dramatic repertoire without proving exactly how it was staged. A modern performance may preserve an older narrative without being an unchanged medieval survival. The object of study is the changing institution of performance itself.

50.2 Dramatic evidence survives in unequal layers

Archaeology rarely preserves a temporary stage, painted backdrop or performer's garment. Manuscripts may survive because they entered libraries, while popular scripts, memorized parts and inexpensive booklets disappear. Court records privilege patrons; literary histories privilege authors; ethnography may record only the late life of a tradition. The archive therefore systematically overrepresents durable and elite materials. A responsible history combines play texts, manuscript colophons, stage directions, courtly and religious contexts, references to performers, printed ephemera, and where available recorded performances. Absence of a surviving script is not proof that theatre did not occur, and possession of a script is not proof of a continuous troupe. The evidentiary asymmetry is itself part of the social history.

50.3 The Nāṭyaśāstra provides concepts, not a local transcript

Bharata's Nāṭyaśāstra remains indispensable for the language of rasa, gesture, costume, music, character type and theatrical convention. Yet it is a pan-Indian normative treatise with a long and complex textual history, not an ethnographic description of medieval Mithila. Later dramatists could inherit, adapt or selectively cite its conventions while performing in different spaces and for different audiences. Terms such as nāṇḁ, sūtradhāra, nāṭī, abhinaya and āhārya can therefore illuminate dramatic structure, but they should not be used to reconstruct an imaginary permanent Sanskrit theatre building in every regional centre. Regional evidence begins where texts, manuscripts, patrons, linguistic choices or performance records anchor those concepts to a historically located practice.

50.4 Jyotirīśvara's Dhūrtasamāgama is a crucial early dramatic witness

Dhūrtasamāgama, associated with Jyotirīśvara Ṭhākura and the Karnata courtly world of early fourteenth-century Mithila, is the most important early surviving dramatic witness for the region. Modern manuscript scholarship describes it as a satirical prahasana that combines Sanskrit and Prakrit dramatic material with Maithili songs and survives in manuscript traditions extending into Nepal. Its value is double. As literature it represents comic social types, dispute, desire, mendicancy and urban encounter; as theatre it demonstrates that learned dramaturgy and vernacular song could coexist in one dramatic architecture. What it does not give us is a filmed performance or complete production dossier. The historian must distinguish the text's performative design from the exact circumstances of any particular staging.

Figure 196 — Evidence ladder for theatre history

50.5 Comedy makes social difference audible

Prahasana works through contrast. Different characters can be marked by speech register, occupation, bodily conduct, moral pretension or social vulnerability. In a multilingual region, linguistic contrast can become theatrical material: Sanskrit may carry learned authority, Prakrit may mark conventional dramatic roles, and vernacular song may create immediacy or local recognition. This does not yield a simple language-to-caste dictionary, because dramatic language is stylized and genre-bound. It does, however, reveal that audiences were expected to recognize differences in register and social persona. Theatre therefore belongs to language history as well as literary history: it stages hierarchy, mimicry and negotiation rather than merely describing them.

50.6 A courtly text is not only court propaganda

Royal patronage matters because courts could support poets, musicians, ritual specialists and manuscript production. Yet the social world represented in comedy extends beyond kings and scholars. Servants, mendicants, brokers, women, performers and urban figures enter the dramatic field precisely because theatre converts social difference into interaction. The court may have financed or received a work without exhausting its meanings. Conversely, the presence of ordinary characters in a play does not prove that ordinary people attended a particular court performance. Patronage, representation and audience must therefore be kept separate. This distinction prevents both an elite-only history of theatre and an equally unsupported claim that every court drama was popular public theatre.

50.7 The project assigns Gorakṣavijaya to the later Vidyāpati Ṭhakkura

This volume maintains its adopted two-Vidyāpati framework. Gorakṣavijaya belongs here to the later Vidyāpati Ṭhakkura associated with the Oiniwar courtly and Sanskrit-Avahaṭṭa intellectual world, not to the earlier Mahākavi Vidyāpati of the Maithili Padāvalī. The play is especially important because its Sanskrit and Prakrit frame is interwoven with Maithili songs in a narrative of Gorakhnātha and Matsyendranātha. Modern scholarship commonly attributes the work to a single fifteenth-century Vidyāpati, while some

scholarship has questioned the authorship of the fully realized play. This volume states its own attribution rule explicitly rather than turning it into a claim of universal scholarly consensus.

50.8 Gorakṣavijaya shows a stronger vernacular dramatic presence

Compared with a predominantly classical-language dramatic frame, Gorakṣavijaya gives the vernacular song sequence a larger narrative burden. Songs do not merely decorate a story; they help move it, characterize religious conflict and organize performance. That feature is central to the later Kīrtaniyā dramatic tradition, where music, recitation, dialogue and gesture form one event. The manuscript itself still cannot tell us whether every performance used the same melodies, tempo, cast or choreography. It does show that the boundary between “play” and “song performance” was structurally porous. This is one reason Chapter 49 and the present chapter overlap: music is not accompaniment added after drama, but one of the means by which dramatic action becomes public.

50.9 Kīrtaniyā drama is a performance system, not merely a genre label

Kīrtaniyā nāṭaka is best understood as an institutional arrangement joining devotional narrative, sung verse, dialogue, gesture, musicians and a troupe. Literary histories often identify professional or semi-professional Kīrtaniyā performers and connect the tradition with Maithili devotional drama. The social implications are significant. Performance required training, memory, musical coordination, travel, patronage or payment, and access to occasions at which a troupe could gather an audience. Such labour complicates the familiar division between “classical” court art and anonymous “folk” expression. A troupe may serve a noble household on one occasion and a broader public gathering on another; the same story can move between prestige and popular settings.

50.10 Umāpati Upādhyāya’s Pārijātaharaṇa became a key dramatic text

Umāpati Upādhyāya’s Pārijātaharaṇa is central to the history of Maithili dramatic writing. George A. Grierson edited and translated the work in 1917, and later Maithili editions kept it within the regional literary canon. Its Kṛṣṇa narrative, frame conventions and substantial Maithili song material make it especially useful for understanding the relation between Sanskritic dramaturgy and vernacular performance. The text has long been associated with Kīrtaniyā presentation, but the date of a composition, the date of a surviving manuscript and the date of a documented performance are not interchangeable. The safest historical claim is that the work became an important dramatic repertoire and that later performance traditions treated it as performable devotional theatre.

Figure 197 — Kirtaniya dramatic architecture

50.11 Dramatic structure can survive even when staging changes

A nāndī, introductory frame, character entrance or repeated song cue can remain legible across centuries even when the performance environment changes. A manuscript copied for reading may preserve instructions created for staging; a printed edition may stabilize words while living performers continue to alter delivery. Theatre history therefore needs two chronologies: the history of the dramatic structure and the history of its realizations. The distinction is especially useful for Pārijātaḥaraṇa and related repertoire, where the surviving text preserves classical conventions but modern recollection of Kīrtaniyā performance may emphasize song, devotional affect and troupe practice. Neither chronology should be allowed to erase the other.

50.12 Performance spaces were flexible and socially differentiated

The region does not require a permanent proscenium building in order to possess a theatrical culture. Court halls, temple or shrine precincts, courtyards, festival grounds, temporary platforms and open public spaces can all host dramatic events. Each setting changes audience composition and authority. Court performance can foreground patronage and etiquette; ritual performance can embed theatre in worship; a fair can create a mixed temporary public; a courtyard can intensify proximity between performer and spectator. Because direct architectural evidence for specific medieval performances is scarce, these spatial categories should be treated as historically plausible types only when connected to texts or later documentation. Chapter 51 examines fairs and public culture more directly.

50.13 Costume and props are evidence only when they are actually attested

Dramatic texts can mention ornaments, weapons, ascetic marks, crowns, veils or distinctive costume, while sculpture and painting can provide a wider visual vocabulary. Yet a pictured deity is not automatically a theatre costume manual. The āhārya dimension of performance must be reconstructed by triangulating textual stage cues, object history, regional dress evidence and later performance documentation. This is particularly important for mythological theatre, where modern costumes may draw on calendar art, cinema

and manufactured materials unavailable to earlier performers. The historical task is not to make the past look theatrically complete; it is to identify what can be dated and to leave the rest open.

50.14 Gesture turns speech into embodied social action

Entrances, glances, movement, dance and comic bodily exaggeration are not secondary to dialogue. They determine status, desire, fear, authority and ridicule in the moment of performance. Classical dramaturgy offers a rich vocabulary for embodied expression, but regional practice can simplify, recombine or vernacularize gesture. A song may be acted, a dialogue may be rhythmically delivered, and devotional movement may shift the event toward *kīrtana*. This embodied dimension helps explain why the written archive always understates theatre: the page records only a fraction of what spectators experienced. Where no choreography survives, the historian should analyze the functions implied by the text rather than invent precise gestures.

50.15 The Nepalmandala archive is central to Maithili theatre history

The movement of manuscripts, scholars and courtly practices across the plains-Himalayan corridor made Nepalmandala one of the major archives of Maithili dramatic culture. Surviving manuscripts in Nepal preserve works whose composition or earlier circulation belonged to Mithila, while Malla courts themselves became productive centres of Maithili dramatic writing. This is not a marginal afterlife of a “pure” tradition located elsewhere. It is a connected history in which languages, scripts, patrons and stage conventions were reassembled in new political settings. The archive therefore prevents a modern national border from being projected backward onto the history of Maithili performance.

50.16 Bhaktapur developed a substantial Maithili court-stage tradition

Ramawatar Yadav’s study of medieval Maithili stagecraft in the Nepalmandala identifies Bhaktapur as a major school of dramatic production. The seventeenth-century Malla court generated numerous plays in Maithili, alongside Newari and other literary activity. Stage directions, multilingual manuscripts and named royal authors provide unusually dense evidence for theatre as an institutional court practice. The significance extends beyond royal authorship. A play presupposes scribes, singers, actors, musicians, rehearsals, costumes and audiences, even when the archive names the king more clearly than those workers. Reading the court archive socially therefore means recovering the hidden production system behind the celebrated author.

50.17 Jagajyoti Malla marks an important linguistic transition on the Nepal stage

Modern scholarship on Nepalese drama identifies Jagajyoti Malla of Bhaktapur as an important early seventeenth-century patron-author in the shift toward Maithili as a court dramatic language. Works attributed to him include Maithili plays such as *Muditakuvalayāśva-nāṭaka* and *Haragaurīvivāha-nāṭaka*. The larger importance is not a list of titles but the linguistic ecology of performance: Maithili could function as a prestige dramatic medium in a Newar-speaking court. Such use demonstrates cultural circulation rather than ethnic replacement. A court can stage a language because of literary prestige, performer networks, repertoire or political-cultural connection without making that language the everyday speech of the entire population.

50.18 Jagatprakāśa Malla shows how Maithili and Newari dramatic creativity could coexist

Jagatprakāśa Malla’s seventeenth-century oeuvre is especially revealing because he wrote in both Maithili and Newari. Recent scholarship emphasizes that Maithili had an established courtly dramatic role even as

Newari literary creativity expanded. This bilingual productivity dissolves a false choice between “local” and “imported” culture. Performance traditions can overlap: a court may inherit one prestigious dramatic language, cultivate another as mother tongue, and draw music or ritual from still wider networks. The theatre history of Nepalmandala is therefore a history of multilingual competence and selective patronage, not a sequence in which one language simply replaces another.

Figure 198 — Mithila-Nepal dramatic corridor

50.19 Royal authorship hides collective theatrical labour

When a king’s name survives on a play, the archive can make theatre look like solitary literary composition. Actual staging requires far more people. Musicians keep time; singers carry lyrics; actors memorize and improvise; dressers and craftsmen prepare appearance; scribes copy or prompt; attendants manage space and objects; patrons finance the event. Some roles may be hereditary or professional, others temporary. The absence of names for these workers is not evidence of their absence. Theatre history must therefore distinguish authorship from production. This is also a social-history correction: artistic prestige often rises upward toward a patron while labour disappears downward into anonymity.

50.20 Manuscript stage directions are small but powerful evidence

A brief instruction such as “enters,” “sings,” “dances” or a note identifying a character can reveal how a text imagined action. In Nepalese manuscripts, stage directions may appear in a language different from the main dialogue or songs, documenting the practical multilingualism of production. Their evidentiary value is high because they point beyond reading toward enacted sequence. Yet even stage directions can be copied conventionally from earlier models. They should be assessed alongside the manuscript’s date, scribal context and local dramatic corpus. The most persuasive reconstruction emerges when formal directions, song structure and a known theatrical environment support one another.

50.21 Gender on the stage cannot be reconstructed from character lists alone

Plays contain queens, heroines, attendants, goddesses, ascetics and female comic figures, but the sex or social identity of historical performers is often not recorded. A female role does not prove a female actor, and a male-dominated manuscript archive cannot prove that women never participated in performance.

Household song traditions show women's major role in regional performance culture, but that evidence cannot simply be transferred onto court theatre. The correct method is to separate character gender, performer gender and audience gender, and to state uncertainty where the record is silent. This prevents later assumptions about respectability or troupe custom from becoming invented medieval facts.

50.22 The sacred and the comic frequently occupy the same performance ecology

Devotional theatre is not necessarily solemn, and comedy is not necessarily secular. Kṛṣṇa narratives can include teasing and rivalry; Śaiva or Nāth narratives can stage temptation and bodily humour; prahasana can criticize religious pretension while remaining embedded in a religiously literate world. Kīrtaniyā performance especially demonstrates how worship, entertainment and social assembly can converge. This hybridity matters for audience history. People may attend for devotion, music, spectacle, patronage, sociability or laughter at the same event. Modern genre labels that separate "religious ritual" from "theatre" too sharply can therefore obscure the actual historical institution.

50.23 Anga's Bihula–Bishahari complex belongs to dramatic history as well as ritual history

In the Bhagalpur–Champanagar cultural zone, Bihula–Bishahari performance combines narrative, song, ritual sequence, costume, image and public assembly. Contemporary scholarship and regional documentation describe a folk-theatre dimension within the larger Manasā/Bishahari ritual complex. Its present form should not be projected unchanged into ancient Anga, but its documented modern ecology is historically significant. It shows how dramatic action can remain attached to shrine, festival and narrative memory rather than separating into a ticketed theatre building. The tradition also demonstrates the permeability among Chapters 47–50: image-making, song, ritual object and theatre can participate in one seasonal complex.

50.24 Narrative theatre creates temporary publics

A performance gathers people who may not otherwise share one institutional space. Spectators respond, donate, joke, move, remember and sometimes interrupt. Vendors, musicians, ritual specialists and patrons create an economy around the event. Temporary public formation is especially important in fairs and festival settings, where theatre is one attraction among exchange, worship and sociability. The stage thus becomes an economic and political space as well as an artistic one. This is the bridge to Chapter 51: public culture is produced not merely by the existence of a market or fairground but by recurring practices that make strangers into an audience for a limited time.

50.25 Print changed drama from an event-memory into a reproducible object

Manuscripts can circulate, but print multiplies identical or near-identical copies, creates title pages, prices, advertisements and new reading publics. A play can now be bought by someone who never sees it performed. Print also changes authority: editors establish a text, literary histories classify it, and schools or associations can revive it from the page. In colonial Mithila this process helped create modern drama while also recasting older Kīrtaniyā and classical models. The printed play therefore belongs simultaneously to theatre history and book history. Its survival may reflect the economics of a press more than the popularity of a stage production.

50.26 The late nineteenth century produced both revival and formal experimentation

Literary historians often place Jīvan Jhā and other late nineteenth-century writers near the beginning of modern Maithili drama, while figures such as Candā Jhā reworked older dramatic and Sanskrit conventions. The period should not be narrated as a clean break from “traditional” to “modern.” Revival, reform, print, new urban audiences and changing notions of literary authorship coexist. A drama can imitate older frames while addressing current social concerns; another can adopt act divisions and prose dialogue yet retain songs. Modernity here is a rearrangement of media and institutions rather than the instant disappearance of Kīrtaniyā performance.

50.27 Brij Bihari Lal Mandal’s Mithilā Nāṭak exposes an excluded print public

Pranav Prakash’s recent study of Brj Bihārī Lāl Maṇḍal’s Mithilā Nāṭak is important because it changes who appears in the history of Maithili theatre. One thousand copies were printed by Krishna Press in Bhagalpur on 2 February 1901. Mandal identified himself with a cowherd caste background, and the chapbook combined social satire, songs, multilingual print conventions and references to performers. Its later neglect demonstrates how canon formation can erase inexpensive and socially marginal print. The example is methodologically decisive: theatrical history cannot be reconstructed only from authors who entered elite literary histories.

50.28 Modern theatre inherits several pasts at once

Twentieth- and twenty-first-century Maithili theatre can draw simultaneously on Sanskrit dramaturgy, Kīrtaniyā song-drama, colonial print, social-reform plays, folk narratives, proscenium technique, radio, film and contemporary festival circuits. A modern director may revive an old title while radically altering duration, casting, music and scenography. Such performance is neither “inauthentic” nor proof of unchanged continuity. It is historical reuse. The same principle applies to staged Vidyāpati, Salhesh, Bihula or mythological narratives: what matters is identifying which layer is inherited, which is reconstructed, and which belongs to present theatrical practice.

50.29 Method: separate text, manuscript, staging, repertoire and memory

Five dates may coexist in a single theatre history. A story can be ancient; a play may be composed centuries later; the surviving manuscript may be later still; a documented staging may belong to another period; and present performers may remember an additional lineage. Historians create false continuity when they collapse these dates. This chapter therefore applies an evidence firewall: text establishes dramatic design, manuscript establishes a witness, stage directions suggest intended action, performance records establish an event, and oral memory establishes remembered continuity. Strong historical claims require more than one layer whenever possible.

50.30 Conclusion: dramatic culture is an infrastructure of social imagination

Across Mithila, Vajji and Anga, theatre has joined language, music, devotion, satire, patronage, craft and public assembly. Its history runs through learned prahasana, vernacular song-drama, Nepalmandala court production, ritual narrative, printed chapbooks and modern stages without becoming a single unbroken form. The durable continuity is not a fixed script or costume but the repeated social act of turning story into embodied encounter before an audience. By keeping evidence layers distinct, we can recognize long regional creativity without inventing timeless institutions. Theatre thus belongs at the centre of socio-cultural history:

it makes hierarchy visible, allows critique to be voiced, creates temporary publics and converts memory into shared action.

Figure 199 — Theatre across changing media

Table 50.1 — Evidence domains for reconstructing theatre and dramatic cultures

Evidence domain	What it can establish	Principal limit
Play text	roles, dialogue, songs, dramatic sequence	does not prove an actual staging
Manuscript witness	date/location of copying, scribal and script history	may be centuries later than composition
Stage directions	entrances, song/dance cues, practical sequence	can be conventional or copied
Court / patron record	institutional support, named authors, political setting	underrecords performers and labour
Visual / material evidence	costume vocabulary, instruments, spatial possibilities	not automatically theatrical
Printed play / chapbook	print run, price, readership, canon formation	reading and performance are different histories
Recorded / witnessed performance	event, cast, venue, audience, embodied practice	cannot be projected backward unchanged

Chapter 51 — Fairs, Markets and Public Culture

51.1 Periodic exchange created a different kind of public space

A weekly haat, an annual mela and an everyday bazaar were not interchangeable institutions. Their calendars, catchment areas and social expectations differed. A haat concentrated ordinary exchange on one or two days and linked surrounding villages to itinerant traders, cultivators and petty retailers. A mela usually gathered a much larger and more heterogeneous public around a ritual date, shrine, river crossing, seasonal need or established custom. Permanent bazaars provided continuity between these periodic concentrations. The social history of Mithila, Vajji and Anga therefore requires attention to time as well as place: the same field, ghat or roadside could be ordinary space for most of the year and become a dense temporary town when a fair opened.

51.2 Markets were also theatres of information

Exchange moved more than grain, cloth, cattle or utensils. Market days brought together people who lived in different villages, worked in different occupations and possessed different news. Prices, crop conditions, marriage prospects, legal disputes, employment, political rumours, pilgrimage routes and performances could circulate through the same gathering. Anand A. Yang's study of Gangetic Bihar is especially valuable because it treats the bazaar as a social and political institution rather than as a neutral container for buying and selling. This chapter follows that insight while keeping the regional histories of Mithila, Vajji and Anga distinct. A market was simultaneously an economic node, a communication node and a public stage.

51.3 The archive overrepresents spectacular fairs

Large fairs generated administrative reports, travel accounts, police arrangements, sanitary records, photographs and later tourism publicity. Small village gatherings often left only a name in a settlement report or census schedule. This imbalance can distort historical reconstruction. Yang's reading of twentieth-century Bihar census material shows that the overwhelming majority of melas were small "fairlets" drawing mainly from nearby villages even though famous events such as Sonepur dominated public memory. The ordinary history of public culture therefore lies as much in modest periodic gatherings as in celebrated mega-events. Scale must be established from evidence rather than inferred from fame.

51.4 Archaeology can identify exchange without identifying a mela

Coins, weights, roads, river landings, storage areas, concentrations of craft debris and imported ceramics can show that exchange occurred. They do not automatically reveal the calendar or social form of that exchange. Ancient Vaishali and other early urban sites in the wider region certainly participated in networks of circulation, but a concentration of commerce is not proof of a named annual fair. Likewise, a pilgrimage tradition recorded in literature cannot by itself demonstrate a livestock market of later historical form. For early periods the safest method is to reconstruct places and circuits of exchange first, and to reserve the word mela for contexts in which periodic assembly is actually supported by textual or later documentary evidence.

Figure 200 — Evidence ladder for fairs and markets

No single source establishes the whole history of a periodic public.

Figure 200 — Evidence ladder for fairs and markets

51.5 River crossings made exchange visible

The Ganga, Gandak, Kosi and their tributaries were not only geographical boundaries. Ghats, ferries and confluences concentrated movement. A river crossing gathered boatmen, pilgrims, traders, porters, animals, tax collectors and vendors at predictable points. Such places could acquire shrines, rest houses and bazaars precisely because people already had to pause there. The confluence at Sonapur and the Ganga crossing at Sultanganj are later, well-documented examples of this relationship between sacred geography and circulation. The wider principle is older: transport infrastructure and ritual geography often reinforced one another, producing public spaces whose economic importance cannot be reduced to either trade or religion alone.

51.6 Weekly haats were the low-threshold infrastructure of rural exchange

The weekly or twice-weekly haat connected cultivators and households to wider circuits without requiring a journey to a town. Grain, vegetables, fish, livestock, fuel, cloth, tools and small manufactured goods could be exchanged in quantities suited to ordinary rural budgets. Petty traders moved between haats, linking one marketing area to another. These gatherings also provided services that were difficult to sustain every day in a small village. Colonial surveys described and counted such markets because they mattered to revenue, transport, policing and prices, but their importance was not created by colonial documentation. The records instead reveal an existing countryside structured by recurring points of exchange.

51.7 Annual melas enlarged the catchment area

A mela could draw people beyond the ordinary marketing radius of a weekly haat. The combination of ritual timing, entertainment and unusual goods made a longer journey worthwhile. Sellers could offer animals, textiles, ornaments, books, religious objects, tools or luxury goods unavailable in small local markets. Performers and service providers followed the crowd. The annual rhythm also allowed households to plan purchases that could not be made from weekly income. In this sense, the mela interrupted the ordinary trade cycle and temporarily raised the market order of its site. The extraordinary character of the gathering was

therefore produced by concentration: more people, more goods, more information and more spectacle in a limited period.

51.8 Sonapur joined pilgrimage, livestock and long-distance trade

Sonapur, at the Ganga-Gandak confluence, provides the clearest Bihar example of a fair whose religious and commercial functions became inseparable. The Kartik Purnima pilgrimage to Harihar Kshetra brought a large public together, while livestock exchange made the event important to agrarian and transport economies. Nineteenth-century descriptions analysed by Yang show separate market areas, rows of stalls and specialized livestock sections, with goods arriving from distant production centres. Modern Bihar tourism continues to present Sonapur as both pilgrimage and fair. The chronology of particular claims about its ancient origin must remain cautious, but its documented colonial and modern history securely demonstrates how ritual gathering could sustain a very large temporary commercial city.

51.9 Livestock fairs were tied to the agricultural calendar

Animals were productive capital. Bullocks ploughed fields and transported crops; cows and buffaloes supplied milk; horses and elephants served transport, prestige and military needs in different periods. A livestock fair therefore linked public culture to the material requirements of agriculture. Yang notes that the timing of major cattle fairs corresponded to seasonal demand and that animals purchased at Sonapur entered wider circuits extending into Bengal. The fairground was also an arena of inspection, bargaining, credit and display. Decorative presentation and riding trials could be entertainment for spectators, but they were also commercial technologies for making an animal's quality visible to prospective buyers.

51.10 The fair converted shopping into spectacle

A fair distinguished itself from routine commerce by making abundance visible. Rows of stalls, unusual animals, novelty goods, performers, food sellers and temporary amusements turned exchange into a sensory event. Nineteenth-century descriptions of Sonapur emphasize the breadth of commodities and the organization of specialized bazaars. The point is not merely that “everything” was available, but that people encountered goods from outside their normal consumption world. Such encounters could reshape taste and aspiration. The mela therefore participated in cultural change by bringing distant styles, objects and practices into a shared public arena where they could be compared, admired, purchased or rejected.

Figure 201 — How a mela creates a temporary public*Figure 201 — How a mela creates a temporary public*

51.11 Small fairs mattered because they were local

Famous fairs connected regions; small fairs connected neighbours. Their modest scale could make them more socially embedded than a spectacular pilgrimage centre. A village fair might coincide with a local deity's festival, a seasonal rite or a small cattle market and draw the same cluster of villages year after year. Because travel costs were low, women, children and poorer households could participate more readily than in a distant long-duration journey, although access still varied by custom and social position. Repetition created familiarity: sellers learned where customers would gather, performers knew where patronage existed, and households incorporated the event into an annual calendar of purchases, visits and obligations.

51.12 Saurath Sabha was a public assembly rather than an ordinary market

The Saurath Sabha in Madhubani is best analysed as a specialized public institution of matrimonial negotiation, not simply as a "marriage fair." Modern field research documents an annual gathering in which Maithil Brahmin families, genealogists and intermediaries meet in a defined assembly space. Exchange here concerns information, lineage verification, status, alliance and negotiation rather than the sale of goods. The Sabha therefore broadens the meaning of public culture: a periodic gathering can organize social reproduction as effectively as a haat organizes commodity exchange. Claims about its precise medieval foundation are repeated in later tradition and should be distinguished from the securely documented modern institution.

51.13 Panji knowledge became public procedure at Saurath

Chapter 31 examined the Panji tradition as a genealogical institution. At Saurath, genealogical knowledge enters a public procedure. Panjikars or genealogical specialists help determine whether proposed marriages satisfy rules of lineage and prohibited relationship. The gathering thus depends on documents, memory, specialist authority and face-to-face negotiation. This is not evidence that every medieval Panji practice occurred in the modern Sabha form. It shows instead how genealogical institutions could be spatialized in a later public assembly. The history of the Sabha must therefore keep two chronologies separate: the history of

Panji recordkeeping and the history of the particular annual gathering through which such expertise came to be publicly exercised.

51.14 Public assembly did not mean equal access

A crowded gathering can create contact without creating equality. Markets and fairs were structured by gender, caste, class, occupation, credit and spatial custom. Sellers with capital could command larger stalls; landholders and officials could exercise regulatory power; itinerant vendors might occupy marginal spaces. Saurath Sabha is a particularly clear reminder that participation rules could be gendered and community-specific even when negotiation took place in an open grove. A social history of public culture must therefore ask who was visible, who spoke, who handled money, who performed, who provided labour and who remained absent from the surviving record. “Public” describes a mode of assembly, not universal citizenship.

51.15 Sultanganj shows how pilgrimage can build a temporary service economy

In the Anga region, the Shravani Mela at Sultanganj demonstrates the economic consequences of concentrated pilgrimage. Pilgrims gather at the Ganga, collect water and begin the journey toward Deoghar. The modern event requires ghats, shelters, food and ritual-supply vendors, transport, sanitation, medical facilities, policing and crowd management. Bhagalpur district’s official Shravani Mela arrangements list health camps, parking, accommodation, control rooms and even regulated rates for food and puja materials. These contemporary records should not be projected unchanged into earlier centuries, but they clearly show how a ritual route can generate a recurring temporary urban economy around movement rather than around permanent settlement alone.

51.16 Pilgrimage corridors redistribute commerce along a route

A pilgrimage economy does not end at the main shrine. Water points, rest places, ferry crossings, roadside markets and temporary camps distribute demand over an extended corridor. Vendors choose locations according to pedestrian flow, transport access and the rhythm of the journey. The Sultanganj-Deoghar route makes this especially visible, but the principle applies more broadly to river and shrine networks across Mithila, Vajji and Anga. Public culture is therefore linear as well as nodal. Songs, slogans, dress, ritual objects and food circulate with pilgrims, while local residents adjust services to predictable seasonal traffic. The route becomes a temporary cultural geography renewed each year.

51.17 Anga’s Bihula-Bishahari cycle links ritual gathering to local commerce

The Bihula-Bishahari complex discussed in Chapters 47, 49 and 50 also belongs to the history of fairs and public culture. In the Bhagalpur-Champanagar zone, ritual observance, Manjusha imagery, narrative performance, procession, offerings and temporary vending can converge around festival time. The commercial dimension should not be mistaken for the origin or essence of the rite. Rather, recurring public worship creates demand for images, materials, food, transport and performance labour. Artisans and performers gain a seasonal market because a ritual public assembles. This is another example of the reciprocal relationship between cultural practice and local economy: neither can be reconstructed adequately while treating the other as background.

51.18 Janakpur turns festival into a cross-border public

Janakpur’s Vivah Panchami is a contemporary example of Mithila’s public culture operating across the India-Nepal border. Nepal Tourism Board describes a week-long festival with wedding reenactments,

processions, music, dance and visitors from nearby Indian cities as well as Nepal. The Janaki Temple precinct and surrounding bazaars become part of a large ritual and commercial environment. The present form is shaped by modern transport, municipal organization and tourism promotion, and it should not be treated as a direct survival of an unchanged ancient festival. Its significance lies in showing how a shared narrative tradition can organize cross-border movement, performance, shopping and civic identity in the modern Mithila region.

Figure 202 — Four public-culture nodes in the connected region

Figure 202 — Four public-culture nodes in the connected region

51.19 Bazaars around pilgrimage centres sell identity as well as goods

Religious objects, printed images, textiles, local foods, toys, paintings and souvenirs allow visitors to carry away material signs of a pilgrimage or region. Janakpur's contemporary bazaars, for example, sit beside temples, ponds and Mithila-art institutions. The commodity can therefore function simultaneously as useful object, ritual aid and marker of place. Similar dynamics operate at fairs throughout the region. This process does not reduce religion to commerce. It shows that material culture mediates memory. A purchased image or locally distinctive object can extend the festival beyond its duration by entering a household, a migrant home or a gift network.

51.20 Fair calendars coordinated sacred and economic time

Periodic gatherings were synchronized with lunar dates, agricultural seasons, marriage seasons or pilgrimage months. This coordination gave traders a predictable calendar and allowed households to combine ritual obligation with practical exchange. Sonepur's Kartik timing, Sultanganj's Shravani cycle, Saurath's marriage-season assembly and Janakpur's Vivah Panchami illustrate different temporal logics. A fair calendar could also link several markets in sequence, allowing livestock dealers, itinerant merchants or performers to move from one gathering to another. Time itself became infrastructure: the date told participants when a temporary market would exist and where dispersed populations could be expected to converge.

51.21 Roads, ferries and railways enlarged fair catchments

Transport technology altered who could attend and what could be sold. River transport and ferries supported older circuits; metalled roads and railways reduced travel time, increased freight capacity and

connected periodic gatherings to distant suppliers. Railway access could transform a local pilgrimage into a regional event without changing its ritual calendar. It also allowed perishable foods, printed matter and manufactured goods to enter in larger quantities. The growth of transport should therefore be analysed as a change in the geography of public culture, not only as an economic modernization story. A mela's crowd and commodity range were partly functions of the networks that delivered people and goods to the site.

51.22 Colonial enumeration made fairs legible to the state

District gazetteers, settlement reports, police files and censuses counted fairs because large gatherings mattered to taxation, disease control, transport, livestock supply and public order. This documentary attention is invaluable to historians, but it was never neutral. Classification converted diverse local events into administrative categories such as fair, market, cattle fair or pilgrimage. Attendance estimates could be rough, and an official interest in sanitation or policing might overshadow participants' own meanings. The archive therefore provides both evidence and a history of state perception. A fair becomes visible twice: once as lived gathering and again as an object of administrative knowledge.

51.23 Sanitation and policing turned the temporary crowd into a governance problem

Large gatherings create concentrated needs for water, waste disposal, medical care, traffic control and security. Colonial authorities increasingly watched fairs through the lenses of epidemic disease, gambling, tax collection, communal tension and political mobilization. Modern district administrations continue the logistical function through control rooms, health camps, parking plans, shelters and rate regulation. The continuity is institutional rather than ideological: the reasons and technologies of governance have changed. The important social fact is that a temporary public can become large enough to require a temporary state apparatus alongside its temporary market.

51.24 Sonepur became a political stage because it already had a crowd

The political history of Sonepur demonstrates that mass gatherings could be repurposed without ceasing to be religious or commercial. Yang documents political meetings at the fair in the nineteenth century, the formation of the Bihar Provincial Congress Committee there in 1908, and Kisan Sabha organizing efforts in the early twentieth century. Political actors chose Sonepur because the fair had already solved the difficult problem of assembling people from a wide area. The crowd was not created by politics; politics entered an existing public. This distinction matters because it shows how cultural and economic institutions supplied infrastructure for later mass mobilization.

51.25 The bazaar could carry nationalism, rumour and resistance

Twentieth-century rural markets in Bihar became sites where nationalist messages, boycotts, speeches and rumours circulated through pre-existing exchange networks. Yang's reconstruction of Noncooperation shows why the bazaar was especially powerful: people came for ordinary economic reasons and encountered political communication within the same space. Markets therefore linked local grievances to wider movements without requiring a permanent party office in every village. Yet the same density of communication could also intensify conflict, misinformation or communal tension. Public culture has no automatic political direction. The market amplifies interaction; what circulates through it depends on historical circumstances and competing actors.

51.26 Entertainment was an economic sector of the fair

Musicians, theatre troupes, storytellers, acrobats, circus performers, toy sellers and food vendors could depend on the concentration of spectators created by a mela. The previous chapters treated song and theatre as cultural forms; the fair reveals their labour and patronage structures. Performance requires a paying or donating public, and a fair supplies one. Conversely, entertainment increases the attractiveness and duration of the fair. Modern Sonapur publicity openly combines livestock, shopping, rides, exhibitions and cultural programmes. The relationship is reciprocal: commerce finances spectacle, while spectacle expands commerce. Public culture is therefore an economy of attention as well as an economy of goods.

51.27 State exhibitions changed the meaning of the mela

In the twentieth and twenty-first centuries, fairs increasingly became platforms for departments, cooperatives, development agencies, tourism bodies and cultural institutions. Government stalls could display agricultural technology, health campaigns, handicrafts or welfare programmes. This added a pedagogic layer to the older marketplace. The state no longer appeared only as police, tax collector or sanitary authority; it also presented itself as exhibitor and service provider. Such interventions could preserve and promote local crafts, but they could also select which practices represented the region publicly. The fair thus became one of the places where “heritage” was curated for citizens and visitors.

51.28 Tourism can preserve scale while changing purpose

Modern tourism promotion stabilizes dates, branding and visual identity, and it can draw visitors who have no direct ritual or commercial obligation to attend. Sonapur is promoted as a cultural spectacle; Janakpur’s Vivah Panchami is presented as a major heritage experience; festival programmes circulate online before the crowd arrives. Tourism can sustain hotels, transport, guides, food sellers and artisans, but it can also shift emphasis toward photogenic performance and standardized representation. Historical analysis should therefore distinguish continuity of venue or calendar from continuity of social purpose. The same fair name can survive while the balance among pilgrimage, trade, entertainment and tourism changes substantially.

Figure 203 — From periodic exchange to mass public culture

Layers accumulate; the purpose of a site can change without the name disappearing.

Figure 203 — From periodic exchange to mass public culture

51.29 Method: reconstruct the public from converging evidence

No single source is sufficient for fair history. Gazetteers may list dates and commodities but speak in an administrative voice. Travel accounts can describe spectacle while exaggerating novelty. Census schedules provide scale but flatten local meaning. Oral histories preserve participant memory but often telescope chronology. Photographs show spatial arrangement without explaining transaction rules. Modern websites document present organization rather than origins. The strongest reconstruction emerges when these sources converge. This chapter therefore separates event date, source date, claimed origin and documented practice. It also treats famous cases as examples rather than templates for every local gathering.

51.30 Conclusion: Part VI ends with material culture in motion

Architecture, dress, food, painting, music and theatre become fully social when people gather around them. Fairs, markets and public assemblies bring the material and performative themes of Part VI into motion: buildings become temporary stalls and stages; textiles become commodities and costumes; food becomes festival consumption; painting becomes portable object; music and theatre find audiences; pilgrimage produces routes and crowds. Across Mithila, Vajji and Anga, periodic public culture connected village to town, shrine to bazaar, household to region and region to wider networks. Its history is therefore not an appendix to economic history. It is the history of how exchange, sociability, performance and power became publicly visible at recurring times and places.

Table 51.1 — Evidence domains for reconstructing fairs, markets and public culture

Evidence domain	What it can establish	Principal limit
Archaeology and landscape	routes, ghats, market sites, exchange intensity	rarely establishes a named periodic fair
Gazetteers and settlement records	dates, commodities, attendance, transport, named fairs and haats	administrative categories and uneven estimates
Fair and market statistics	scale, frequency, spatial catchment	counts flatten local meaning and participation
Travel accounts and visual records	layout, spectacle, goods, crowd experience	selective viewpoint and possible exaggeration
Ethnography and oral history	participation rules, memory, specialist roles, lived meanings	present memory can telescope chronology
Political and police records	mobilization, surveillance, conflict, regulation	overrepresents disorder and state concerns
Contemporary official sources	current logistics, programmes, services and tourism framing	cannot establish ancient or medieval origins

PART VII

EARLY MODERN AND COLONIAL ECONOMIC TRANSFORMATIONS

Chapters 52–64

Chapter 52 — Mughal-Period Land, Revenue and Agrarian Society

Mughal rule did not replace the agrarian society of Mithila, Vajji and Anga with a single uniform land system. It superimposed imperial fiscal claims, assignments and administrative categories upon village production, regional chieftaincies, hereditary local offices and ecologies shaped by the Ganga, Gandak, Kosi and their tributaries. The most useful contemporary source, Abu'l-Fazl's *A'in-i Akbari*, gives unusually detailed fiscal statistics for the Bihar subah, including the sarkars of Tirhut, Hajipur and Munger. Yet those figures record assessed revenue and administrative knowledge; they do not by themselves tell us what every cultivator paid, what every zamindar retained, or how much was actually collected in a flood-prone year. This chapter therefore reconstructs Mughal agrarian society through a layered method: official statistics, regional revenue documents, the history of Bihar's zamindars and chieftains, agrarian ecology, and later gazetteer summaries are used together but never treated as interchangeable archives.

52.1 Land revenue is a social relation before it is a statistic

The Mughal state's agrarian income depended on the crop produced by cultivators, but the path from field to treasury passed through multiple claims. Irfan Habib's central warning remains essential: the Mughal land revenue was neither a modern property tax nor simply a landlord's rent. It was a state claim upon agricultural produce, expressed through assessment, rates, measurement, crop estimates and cash equivalents. In regional society this claim interacted with the rights of zamindars, village headmen, hereditary record-keepers and cultivators. To study revenue is therefore to study power, labour and negotiation: who could demand, who could record, who could resist, who advanced cash, and who bore the risk when crops failed.

52.2 The subah–sarkar framework made the region fiscally legible

Under Akbar, Bihar was represented as a subah divided into sarkars, and the connected historical region of this volume cut across several of them. Tirhut organized much of north Bihar; Hajipur controlled a strategically important Ganga–Gandak zone; and Munger incorporated much of the eastern country connected with Anga, including Bhagalpur in the *A'in's* mahal list. These were imperial administrative frames, not timeless cultural borders. Mithila did not cease to exist because Tirhut appeared in Mughal accounts, and Anga's older cultural geography was not identical with Sarkar Munger. The fiscal map must therefore be read as one historical layer among several.

52.3 The *A'in-i Akbari* is an administrative archive, not a census

Abu'l-Fazl's compilation is exceptionally valuable because it records measured land, mahals, assessed revenue and military obligations for many localities. It also describes Bihar's rivers, crops and agricultural abundance. But its precision can create false confidence. A revenue figure is a fiscal claim recorded for administrative purposes; it is not an enumeration of every household, every field or every transfer of grain. Measurement coverage varied, local categories were translated into imperial formats, and the relationship between assessed revenue (*jama*) and realized collection (*hasil*) could be substantial. The *A'in* should be used quantitatively, but with the discipline appropriate to an official fiscal document.

Mughal fiscal geography: administrative scale is not land ownership

Figure 204 — Fiscal geography from subah to village

52.4 Tirhut appears as a large, internally differentiated fiscal unit

In the A'in's Bihar section, Sarkar Tirhut contains seventy-four mahals. It is assigned 266,464 bighas and 2 biswas of measured land and an assessed revenue of 19,179,777½ dams. The same entry records cavalry and infantry obligations, reminding us that fiscal capacity and military service belonged to the same imperial grammar. The seventy-four mahals matter more than a single total: they show that 'Tirhut' was not administered as one undifferentiated estate. It was a mosaic of assessment units whose local histories, cultivation intensity, waterways and intermediaries could differ sharply.

52.5 Hajipur demonstrates the fiscal importance of the river junction

Sarkar Hajipur is listed with eleven mahals, 436,952 bighas and 15 biswas of measured land, and assessed revenue of 27,831,030 dams. The number is larger than Tirhut's recorded assessment even though Tirhut contains many more mahals, a warning against using the count of administrative units as a proxy for productive capacity. Hajipur's position near the Gandak–Ganga junction linked agrarian collection to ferries, routes and commercial movement. Revenue geography was therefore also transport geography: a highly productive riverine zone could be valuable not only because of crops but because it concentrated movement, markets and administrative access.

52.6 Munger connects Anga to a major eastern revenue-military zone

The A'in lists Sarkar Munger with thirty-one mahals and assessed revenue of 109,625,981½ dams; the mahal list includes Bhagalpur and other eastern localities. Modern Munger district history preserves the same broad fiscal profile and notes the sarkar's cavalry and infantry obligations. The scale of the recorded demand is striking, but it should not be converted directly into a measure of peasant welfare or actual annual realization. For this volume, its importance is geographical: the Mughal fiscal history of Anga cannot be reconstructed from Bhagalpur alone. It belongs to a wider Munger-centred administrative and military landscape stretching along the Ganga.

52.7 A 1582 Tirhut–Hajipur assessment offers a second statistical window

The 1907 Darbhanga district gazetteer, drawing on earlier revenue history, states that Todar Mal's 1582 assessment covered 817,370 acres in the sarkars of Hajipur and Tirhut and fixed revenue at Rs 11,63,020. The combined A'in figures, converted at forty dams to the rupee, yield a broadly comparable but not identical magnitude. The difference is analytically useful. Fiscal compilations produced at different dates and through different procedures should not be forced into artificial agreement. Later gazetteers can preserve earlier assessments, but they also translate them into colonial units and administrative concerns. Convergence is evidence; discrepancy is evidence too.

Note: figures are assessed fiscal statistics, not proof of actual collection or equal measurement coverage. 40 dams ≈ 1 Akbar-shahi rupee.

Figure 205 — Akbar-era fiscal profiles of Tirhut, Hajipur and Munger

52.8 Measurement was a technology of rule, not a neutral act

To measure land was to classify cultivation, define assessable area and make local production comparable across administrative units. Yet an alluvial region challenged any ideal of fixed cadastral space. Rivers shifted channels, chars emerged and disappeared, fields flooded, and cultivation moved between low and high ground. The bigha itself was a historical measure whose local value could vary; the A'in's attempt to standardize measures did not erase every regional practice. Measurement should therefore be studied as a state technology applied to a moving landscape, not as a modern survey grid perfectly laid over stable plots.

52.9 Jama and hasil must never be collapsed

Jama was the assessed or sanctioned revenue demand; hasil was what was actually realized. A high jama could indicate fiscal expectations, rich cultivation or administrative optimism, but without collection records it does not prove that the treasury received the full amount. Arrears, remissions, crop failure, local resistance, military disorder and the bargaining power of zamindars could all widen the distance between assessment and realization. This distinction is especially important when comparing Tirhut, Hajipur and Munger. The chapter therefore uses A'in totals as indicators of the fiscal value assigned to regions, not as audited receipts.

52.10 Mughal revenue was a claim on the crop, not modern ownership of soil

European observers often described the Mughal emperor as owner of all land, but this language can obscure the layered character of agrarian rights. Habib emphasizes that the state claim functioned as a tax on agricultural produce and could coexist with cultivator possession, zamindari claims and village-level

customary rights. The existence of a state demand did not erase other rights in land, nor did a zamindar's revenue role make him equivalent to a nineteenth-century Permanent Settlement landlord. The categories of Chapter 55 must not be imported into Chapter 52.

52.11 The peasant household remained the productive centre of the system

Imperial statistics begin with the state, but agricultural production began with households that supplied seed, labour, tools, draught power and everyday risk-bearing. Family labour could be supplemented by hired workers, dependants or service groups. Cultivators decided how much land could be sown, which crops to combine and how to respond to flood, drought, cattle loss or debt. A revenue schedule could influence these decisions, but it could not mechanically determine them. The productive household therefore forms the lowest indispensable scale of analysis beneath every imperial revenue total.

52.12 Village officers translated fields into fiscal records

The Mughal countryside depended on local knowledge. Headmen, patwaris, qanungos, chaudhurs and other intermediaries connected cultivation to accounts, remissions, collections and the authentication of rights. Their functions varied by place and period, but the principle is clear: the imperial state could not inspect every field directly. It governed through people who knew village boundaries, crop histories, customary shares and local families. Such officers could mediate between cultivators and higher authority, but they could also use their informational advantage to consolidate influence.

52.13 Zamindars were political intermediaries, not merely rent collectors

The Mughal term zamindar covered a range of local power-holders, from relatively modest revenue claimants to substantial chiefs with armed followers, forts and territorial authority. Tahir Hussain Ansari's study of Bihar shows how Mughal consolidation depended on negotiation, confirmation and conflict with such chieftains. Their rights could include a share of agrarian surplus, policing or military responsibilities, hereditary status and local patronage. Calling all of them 'landlords' compresses several functions into one modern category and conceals the political character of agrarian extraction.

52.14 The Darbhanga house became one regional node within Mughal fiscal politics

The history of the Darbhanga Raj belongs partly to the Mughal period but should not be read backward from its later colonial scale. Regional traditions and documents associate Mahesh Thakur and his successors with the consolidation of revenue authority in Tirhut under Mughal rule. Ansari reconstructs the house's relationships with imperial and provincial officials, including the role of Gopal Thakur during the Akbar-period survey and settlement. The significant historical point is not that a later great estate already existed in finished form, but that a lineage of learned and revenue intermediaries accumulated recognized fiscal functions over time.

52.15 Qabuliyat, arrears and share transfers reveal the contractual side of revenue

A seventeenth-century dispute discussed by Ansari records a qabuliyat for Tirhut and arrears apportioned among share-holders. When some holders could not meet their portion of the government demand, shares in chaudhuri and qanungo rights were transferred in connection with payment of the outstanding sum. This kind of evidence opens a different window from the A'in. Instead of a top-down total, we see obligation

divided among named holders, arrears producing pressure, and fiscal rights becoming transferable assets. Mughal agrarian society was therefore also a world of contracts, guarantees, debt and negotiated shares.

Agrarian surplus moved through overlapping claims

Figure 206 — Overlapping claims on agrarian surplus

52.16 Khalisa and jagir changed the destination of revenue claims

A large part of the Mughal revenue base was assigned in jagir to mansabdars, while khalisa lands supplied the imperial treasury more directly. This distinction affected who collected or benefited from assessed revenue, but it did not transform the underlying crop into the assignee's private freehold. Jagirdars held assignments whose location could change; they had incentives to secure collection within the terms of office. The political economy of assignment could therefore shape local pressure even when village cultivation continued under older routines.

52.17 Bihar's rice economy was recognized in the Mughal description itself

Abu'l-Fazl's description of the Bihar subah states that agriculture flourished to a high degree and singles out rice for both quality and quantity. This is particularly important for Mithila and the low-lying Gangetic plains, where water abundance could sustain intensive paddy cultivation but also expose crops to flood and channel change. Rice should not be treated as the only crop, yet it anchors the relationship between ecology and revenue: a state seeking agrarian surplus had to adapt its demand to a landscape where water created both fertility and risk.

52.18 Pulses, sugarcane and betel diversified the agrarian base

The same Bihar description mentions khesari, abundant sugarcane and high-quality Maghi betel leaf. These details prevent a monocrop picture of the province. Pulses mattered to subsistence and soil-use cycles; sugarcane was a high-value crop requiring labour and processing; betel linked specialized cultivation to market demand. General Mughal sources also show oilseeds and other commercial crops across north India. The agrarian economy of the connected region therefore combined staple production with crops that moved through wider markets and could attract stronger fiscal interest.

52.19 Commercialization did not begin with colonial indigo

Later chapters will examine indigo, opium and colonial commodity regimes, but it would be equally misleading to imagine a purely subsistence Mughal countryside. The state preferred revenue-rich crops; sugarcane, oilseeds, poppy and other marketable products circulated alongside grain. Cash assessment itself increased the importance of markets because cultivators and intermediaries needed monetary resources to meet obligations denominated in money. Commercialization was therefore already present, though its institutions and coercive mechanisms differed from the nineteenth-century indigo and opium systems.

52.20 Seasonal cropping made revenue dependent on ecological timing

Agriculture followed kharif and rabi cycles, and wetter tracts could sustain multiple crops where water and labour permitted. The fiscal year had to interact with harvest time. A demand poorly synchronized with production could intensify borrowing or force sale at unfavourable moments. Flood, drought and river erosion could alter the cultivable base between assessments. The history of revenue is therefore also a history of calendars: sowing, transplanting, harvesting, collection and remittance did not occur simultaneously, and the gap between them shaped rural vulnerability.

52.21 Expansion of cultivation changed the frontier between field and waste

Mughal-period economic growth in Bihar included expansion of cultivation into areas previously classified as waste, scrub or forest. But ‘waste’ is an administrative category, not proof of empty land. Grazing, fishing, fuel collection, shifting cultivation and seasonal use could occupy spaces not recorded as regularly ploughed fields. Bringing new land under assessment could increase state revenue while narrowing access to common resources. Agrarian expansion therefore redistributed ecological rights as well as enlarging the measured crop area.

52.22 Labour relations extended beyond the category of cultivator

Fields depended on ploughmen, cattle keepers, artisans who repaired tools, transport workers, boatmen, processors of cane and oilseeds, and service communities attached to villages and markets. Some were paid in cash, some in grain, some through customary shares or access to land. The Mughal revenue archive rarely records this labour world in proportion to its importance. A social history of agrarian revenue must therefore reconstruct the workers who made assessed production possible but appear only indirectly in fiscal documents.

52.23 Monetized obligations made credit structurally important

Where revenue was expressed or collected in cash, cultivators and intermediaries needed liquidity before, during and after harvest. Advances, merchant credit, grain loans and arrears therefore belonged to the fiscal system even when surviving documents are fragmentary. The seventeenth-century Tirhut share dispute demonstrates how unpaid government dues could reorder rights among local holders. Debt was not simply a private household problem; it could become a mechanism through which fiscal authority, office and property-like claims were redistributed.

52.24 Revenue pressure and agrarian prosperity could coexist

High fiscal value does not automatically mean misery, and abundant agriculture does not mean light taxation. Mughal agrarian regions could display both substantial production and strong extraction. The relevant question is distribution: how much surplus remained with cultivators after seed, subsistence, local

claims and state revenue; how collection varied by season; and what bargaining resources different groups possessed. This is why aggregate revenue statistics cannot substitute for social history. Prosperity at the level of a sarkar and insecurity at the level of a household are not mutually exclusive.

52.25 Coercion and negotiation were both built into collection

Revenue collection had coercive backing, but the state also depended on cooperation. Zamindars could resist; cultivators could flee or reduce cultivation; local officers could delay, conceal or renegotiate assessments; imperial authorities could remit or reschedule demands. The relationship was therefore neither a free contract nor unmediated force. It was a field of unequal negotiation in which the capacity to mobilize armed followers, local knowledge, credit or imperial patronage could materially alter outcomes.

52.26 Munger's fiscal weight was tied to its strategic geography

Munger was not simply an agricultural hinterland. Its fort, Ganga position and role in eastern military movement linked revenue to strategic control. The A'in's very large assessed revenue and troop obligations should be read together. Bhagalpur and other Anga localities within Sarkar Munger contributed to a fiscal-military corridor connecting Bihar with Bengal. In this setting, agrarian surplus supported more than a treasury: it sustained garrisons, officials, transport and the circulation of armed power along the river.

52.27 Tirhut and Anga faced different ecological combinations inside one imperial province

The connected region should not be flattened into a single 'Bihar agriculture'. North Bihar's floodplains, Gandak and Kosi systems, and dense wet-rice ecologies differed from the Ganga-edge and upland combinations visible farther east around Munger and Bhagalpur. These differences affected crop mix, transport, settlement stability and the cost of measurement. Mughal categories standardized administration across space, but ecological diversity limited how uniform agrarian practice could become.

52.28 The Nepal Tarai was connected to the agrarian zone without being Mughal fiscal territory

The northern cultural and economic world of Mithila crossed the political frontier toward the Tarai/Madhesh, but Mughal Bihar's revenue statistics cannot simply be extended into territories under Nepalese polities. People, cattle, grain, forest products and religious networks crossed boundaries more easily than fiscal sovereignty did. This distinction matters for the India–Nepal scope of the volume: interaction zones can be continuous while political economies remain different. Chapter 65 returns to the borderland economy with the appropriate Nepal-side evidence.

52.29 Method: keep imperial statistics, regional documents and colonial reconstructions in separate columns

A sound reconstruction uses the A'in for late-sixteenth-century fiscal geography; qabuliyat, farmans and regional histories for negotiated rights and obligations; general Mughal agrarian scholarship for analytical categories; and colonial gazetteers only as later summaries that sometimes preserve earlier figures. No source is allowed to silently borrow the authority of another. The famous 1582 Tirhut–Hajipur assessment, for example, is valuable precisely because its later gazetteer transmission can be compared with the A'in rather than substituted for it.

Evidence firewall: do not collapse four different archives

Historical inference is strongest when fiscal statistics, regional documents, agrarian ecology and later summaries converge.

A later archive may preserve an earlier number, but it also carries the categories and purposes of its own period.

Figure 207 — Evidence firewall for Mughal agrarian reconstruction

52.30 Conclusion: Mughal agrarian society was a layered fiscal ecology

Across Tirhut, Hajipur and Munger, the Mughal state made countryside legible through sarkars, mahals, measurement, assessed revenue and recorded obligations. Beneath that grid remained cultivator households, seasonal crops, flood risk, village officers, zamindars, credit relations, local rights and ecological differences. The resulting order was neither a timeless village system nor a preview of the Permanent Settlement. It was a specifically early modern configuration in which imperial extraction depended on local intermediaries and productive landscapes that could never be reduced entirely to the numbers written in a revenue table.

Table 52.1 — Evidence domains for reconstructing Mughal land, revenue and agrarian society

Evidence domain	What it can establish	Principal limit
A'in-i Akbari	sarkars, mahals, measured land, assessed revenue, crops, administrative geography	jama is not identical with actual collection; measurement coverage varies
Qabuliyat, farman, revenue disputes	named obligations, shares, arrears, confirmation of offices and rights	survival is selective and often centred on elites
Regional zamindar/chief histories	political brokerage, hereditary claims, conflict and imperial negotiation	later lineage histories can project continuity backward
Agrarian ecology	crop possibilities, flood risk, transport, seasonal constraints	environment alone cannot establish fiscal institutions
Colonial gazetteers	later summaries of earlier assessments and local administrative memory	translate the past into colonial units and categories
Modern economic history	jama/hasil, zamindar, jagir, surplus distribution, quantitative comparison	general models require regional testing

Chapter 53 — Trade between Bengal, Bihar, Nepal and the Gangetic World

Trade connected the socio-economic worlds of Mithila, Vajji and Anga to regions far beyond their political boundaries. The Ganga formed the principal east–west trunk between the upper Gangetic plain and Bengal; Patna developed as a major inland entrepôt; Munger and Bhagalpur lay on the eastern river corridor; Hajipur and Tirhut fed northward routes toward Nepal; and Kathmandu connected plains commerce with Himalayan and Tibetan exchange. These links were already visible before European companies became major actors, then intensified and changed as English and Dutch merchants entered Bihar’s commodity markets. The evidence, however, is uneven. A late-sixteenth-century traveller, a seventeenth-century factory letter, a 1790s diplomatic mission and Buchanan-Hamilton’s early-nineteenth-century trade account cannot be collapsed into one timeless picture. This chapter therefore reconstructs circulation through securely dated layers: routes, transport, merchants, credit, commodities and market nodes are compared across sources while each observation remains tied to its own period.

53.1 Trade is a network of movements, not a line between two capitals

The commercial history of Mithila, Vajji and Anga cannot be reduced to a single Patna–Bengal route or to a modern India–Nepal border crossing. Early modern exchange worked through overlapping scales: weekly rural markets gathered produce; river landings concentrated bulky cargo; towns provided storage, credit and brokerage; long-distance merchants linked those towns to Bengal, the upper Gangetic plain and the Himalayan world. A commodity could therefore change carriers, forms and destinations several times before reaching a final consumer. The useful unit of analysis is the network—nodes, seasonal routes, intermediaries and transaction costs—not a straight line drawn between political centres.

53.2 The Ganga was the principal east–west transport trunk

For heavy and bulky goods the Ganga offered a transport corridor of exceptional importance. It connected the upper Gangetic cities with Patna and continued east through Munger, Bhagalpur, Rajmahal and the Bengal river system toward Kasimbazar and Hugli. River movement did not eliminate land transport; rather, carts, pack animals, ferries and local feeder routes delivered goods to and from navigable water. The river also changed seasonally. Current, channel depth, monsoon floods and shoals affected speed, boat size and the places where cargo had to be shifted. Trade geography was therefore hydraulic as well as political.

53.3 Ralph Fitch’s journey shows an already integrated late-sixteenth-century corridor

Ralph Fitch’s 1585–86 journey is valuable because it predates the mature European company factory system. Travelling east from Agra, he moved with a large boat convoy carrying commodities down the Yamuna and Ganga, passed Allahabad, Banaras and Patna, and continued into Bengal. His itinerary demonstrates that Patna was already embedded in a long-distance river world before English or Dutch corporate commerce became important there. Fitch should not be read as a complete trade survey, but his route provides a securely dated witness to continuous movement between the Mughal heartland, Bihar and Bengal.

Figure 208 — Trade geography: trunk route and feeder corridors

53.4 Seventeenth-century Patna became an entrepôt rather than merely a producing town

By the seventeenth century Patna's commercial importance rested on its ability to collect, finance, store and redistribute goods from several directions. Peter Mundy's 1632 mission to Patna was itself a commercial experiment: the English sought a market for quicksilver and vermillion and hoped to reinvest the proceeds in saleable Indian goods. Later English and Dutch establishments increasingly focused on commodities procured in Bihar, especially saltpetre, while Patna also handled textiles, opium, grain and other products. Its significance therefore lay in brokerage and through-traffic as much as in manufacture within the city.

53.5 Patna's hinterland extended far beyond the modern district boundary

An entrepôt gathers the output of a wider production zone. Cotton weaving, grain supply, saltpetre manufacture and other activities were distributed through villages and smaller towns whose goods entered Patna through merchants, brokers and periodic markets. The city's accounts consequently mix local production with goods assembled from farther away. This is methodologically important: a commodity recorded at Patna is not automatically a Patna product. The distinction between place of production, place of purchase, place of refinement, place of storage and place of export must be preserved whenever the sources permit it.

53.6 The downstream route tied Bihar to Bengal's inland and maritime economy

The eastward river route ran through the Ganga corridor toward Rajmahal, Kasimbazar and Hugli, with Munger and Bhagalpur lying directly on the connected waterway. Ahmad Raza Khan's source-based reconstruction of seventeenth-century Bihar emphasizes the Patna-Hugli river route and the movement of loaded boats through eastern Bihar. Once cargo reached Bengal's commercial centres, it could be redistributed within the delta or linked to maritime trade. Bihar's inland economy was thus connected to the Bay of Bengal without being a coastal economy itself.

53.7 The upstream route connected Patna to Banaras, Allahabad, Agra and wider north India

Westward and upstream movement was equally important. Patna's merchants and goods were connected by river and road to Banaras, Allahabad and Agra, and through those centres to larger north Indian commercial fields. Khan reconstructs a frequently used Patna–Agra land route through Sasaram, Banaras and Allahabad. The point is not that every merchant followed one prescribed itinerary. Multiple land and river options existed, and merchants chose among them according to season, security, tolls, cargo and market opportunity.

53.8 Northward feeders linked Hajipur and Tirhut to Nepal

Patna's northern commercial field depended on crossings of the Ganga and on routes through Hajipur and the north Bihar plain. Seventeenth-century reconstructions describe a Patna–Hajipur–north Bihar route continuing toward the Himalayan foothills and Nepal. This axis mattered to Mithila because Tirhut was not commercially isolated behind its rivers: its markets and road-ferry combinations formed part of the approach to Nepal. The exact path could vary, but the structural relationship is clear—Patna's east–west river trunk was intersected by a north–south corridor through the Mithila-Vajji zone.

Figure 209 — Patna as an entrepôt

53.9 Nepal evidence must be dated independently from Bihar evidence

The India–Nepal dimension requires a stricter chronology than is often used in regional histories. William Kirkpatrick's late-eighteenth-century mission and Francis Buchanan-Hamilton's early-nineteenth-century account provide detailed information on roads, merchants and commodities moving between the low country, Kathmandu and Tibet. These sources are indispensable, but they belong to their own dates. They can demonstrate the mature structure of a corridor and help identify durable geographical constraints; they cannot by themselves prove that every commodity or volume recorded around 1800 existed in the same proportions in 1650.

53.10 Buchanan-Hamilton identifies Patna as the principal mart for low-country trade with Kathmandu

Buchanan-Hamilton's account is unusually explicit: the route by which he entered Kathmandu was, in his description, the one most frequented by merchants from the low country, especially those trading with Patna, which he called the principal mart for that commerce. This statement belongs to the early nineteenth century, yet it confirms the continued importance of the Patna–Nepal commercial relationship after the Mughal period. Used carefully, it strengthens the interpretation of Patna as a north–south redistribution centre while leaving seventeenth-century quantities to seventeenth-century evidence.

53.11 Nepal and Tibet supplied distinctive high-value goods to the plains

Buchanan-Hamilton records a varied Kathmandu trade in which Tibetan and Himalayan goods included borax, musk, woollen cloth, animal products, medicinal substances and bullion. Some of these goods moved onward to Patna and the low country. Seventeenth-century Bihar evidence independently records borax procurement at Patna and later references to Nepalese borax entering Tirhut. The overlap is significant because it links a commodity named in Bihar commercial records to a Himalayan supply zone, while still requiring caution about changes in route, scale and political control across time.

53.12 Plains manufactures and consumption goods moved northward through the same corridor

The flow was not one-way. Buchanan-Hamilton lists Indian cotton cloths, metal utensils, spices, betel, tobacco and other manufactured or consumption goods entering Nepal from the low country, many of them ultimately traded onward. This reciprocal movement helps explain why a plains entrepôt mattered to Himalayan commerce: Patna was not simply a buyer of northern products but a redistribution point for Indian and imported goods. The trade depended on differences in ecological production, craft specialization and demand across plains, hills and Tibetan plateau.

53.13 Anga's river towns formed part of the corridor rather than a separate eastern economy

Munger, Bhagalpur and the Anga zone lay on the Ganga route between Patna and Bengal. Boats carrying goods east or west therefore passed through an inhabited production landscape rather than an empty transit space. Later trade evidence shows Bhagalpur supplying grain to Patna, while the region also possessed important craft and textile traditions examined elsewhere in this volume. The correct model is a chain of nodes: Anga could produce, consume, transship and redirect goods while remaining tied to larger Bihar–Bengal circuits.

53.14 River transport required transshipment, boat knowledge and labour

The phrase “carried down the Ganges” can conceal the work involved. Different reaches required different craft, pilots and loading practices; shallow water or changing channels could force cargo to be transferred. Boatmen, porters, warehouse workers, ferrymen and river pilots were therefore essential commercial labourers. Their skills converted a river into infrastructure. The social history of trade must include this workforce, even though merchant and company archives usually record them less fully than goods, prices and contracts.

53.15 Roads, sarais and ferries made overland commerce possible

Land routes were supported by ferries, market towns and sarais where merchants could rest, guard goods and obtain supplies. Peter Mundy's description of a Patna sarai used by merchants from distant regions illustrates the cosmopolitan infrastructure of the city. Mughal roads did not function like modern highways: surfaces, security and maintenance varied, and rivers could interrupt a route. Nevertheless, the repeated presence of caravan lodging and commercial halts shows that overland movement was institutionalized rather than improvised anew for every journey.

53.16 Merchants came from many communities and political jurisdictions

Patna's commercial world included local merchants and brokers, Persians and Central Asians, Armenians, merchants from Bengal, and, increasingly, agents of European companies. No single group controlled all commodities or routes. Different merchants specialized in distinct circuits and used partnerships, kin networks, brokers and credit to reduce risk. The presence of foreign merchants should not obscure the larger indigenous commercial structure on which they depended. European companies entered an existing market system; they did not create Patna's long-distance commerce from nothing.

53.17 Credit, money changing and coinage connected distant transactions

Long-distance trade required more than transport. Merchants needed advances, accounting, reliable money, mechanisms for remittance and people able to judge coins and creditworthiness. Patna's commercial growth therefore strengthened bankers, brokers and money changers as well as commodity merchants. Mughal silver currency facilitated exchange across regions, while imported bullion could enter Indian monetary circuits through mints and money markets. Credit reduced the need to move specie with every shipment, but it also concentrated power in merchant and financial networks whose surviving records are uneven.

Figure 210 — Commodity circuits documented in different periods

53.18 Saltpetre linked village production to global demand

Saltpetre became one of Bihar's most internationally significant seventeenth-century exports. It was produced and refined in a regional industry, collected through Patna and nearby centres, and purchased in

large quantities by Dutch and English traders for shipment eastward and overseas. Its history demonstrates how a substance produced from local soils and labour could enter military economies far beyond India. It also shows why a trade history must move across scales: village extraction and refining, merchant procurement, river transport, company contracts and maritime export were parts of one commodity chain.

53.19 Textiles connected Bihar production with Bengal silk and wider Asian markets

Patna was known for cotton goods, while Bengal supplied raw silk and finished textiles to wider commercial networks. Early English ventures in Patna sought cloth, and merchants from multiple regions came to purchase textile products. The textile trade should not be reduced to a European export story. Cloth circulated within India, moved toward Persia and Central Asia through merchant networks, and entered Himalayan markets. Bengal and Bihar were therefore complementary and competing production-commercial regions whose textile circuits overlapped in Patna.

53.20 Opium was already commercial before the Company monopoly

Opium later became inseparable from East India Company monopoly, but its commercial history in Bihar is older. Seventeenth- and eighteenth-century accounts place opium among the commodities handled at Patna, and eighteenth-century merchants traded it through Asian circuits. Chapter 57 examines the colonial commodity network in detail. Here the important point is chronological: Company monopoly reorganized an existing commercial crop and trade rather than inventing opium commerce *ex nihilo*.

53.21 Grain, sugar, oilseeds and salt made ordinary provisioning part of long-distance trade

High-value exports attract attention because European records describe them in detail, but ordinary food and provisioning goods were equally important to regional integration. Grain could move between surplus and deficit districts; sugar and oilseeds entered urban and interregional markets; salt moved inland from supply zones and was redistributed. Later Buchanan estimates for Patna show large two-way flows of staples, confirming that an entrepôt did not merely export luxury or strategic commodities. Food commerce linked peasant production to cities and made transport conditions immediately relevant to subsistence.

53.22 Metals and imported manufactured goods reveal Patna's redistributive function

Copper, lead, zinc, tin and manufactured wares entered Patna from different directions and could then be sent onward to other markets, including northward routes. European traders also tried to sell quicksilver, broadcloth, lead and vermillion in the city. Such transactions demonstrate the difference between production and trade. Patna's importance lay partly in its ability to match goods produced elsewhere with buyers in another region. A commercial centre could therefore prosper through circulation even when it did not manufacture every item in its warehouses.

53.23 European companies were commercial actors before they became territorial rulers

The English and Dutch established factories and procurement systems in Bihar during the seventeenth century, but their political sovereignty came later. In Chapter 53 they must be treated first as merchants with special corporate privileges, capital and overseas shipping connections. They competed with Indian and

Armenian merchants, depended on brokers and producers, and negotiated with Mughal and provincial authorities. Chapter 54 begins when commercial presence becomes entangled with territorial expansion and the remaking of agrarian power. Keeping that boundary clear prevents the entire seventeenth century from being narrated backward from Plassey and Diwani.

53.24 Bengal's early-modern boom increased the value of the Bihar connection

Research on Bengal's seventeenth- and eighteenth-century economy emphasizes agricultural expansion, textile production, urban growth and maritime trade. Bihar's position on the western approaches to Bengal gave it a complementary role: goods, bullion, merchants and information moved between the delta and the upper Gangetic plain through Bihar's river corridor. Patna and Anga therefore belonged to the economic geography of Bengal's expansion without being absorbed into a single homogeneous "Bengal economy." Regional specialization and transit were precisely what made interregional trade profitable.

53.25 Political boundaries and cultural regions overlapped but did not coincide with trade zones

Mughal subah boundaries, the older cultural geographies of Mithila and Anga, the Nepalese polities north of the plains and the commercial reach of Bengal were different spatial systems. Merchants routinely crossed from one into another. Customs points and political authority mattered, but they did not turn each jurisdiction into a closed economy. For this volume, trade is one of the clearest demonstrations that connected history must be mapped with several boundaries at once: fiscal, cultural, ecological and commercial.

53.26 Tolls, customs, brokerage and security shaped the cost of movement

Transport costs were not only the price of boats or carts. Merchants faced customs dues, ferry charges, market fees, brokerage, storage costs and the expense of protecting goods. Political disorder could increase risk premiums or redirect traffic; secure routes and predictable duties could attract it. These transaction costs explain why entrepôts and established routes acquired persistence. A merchant might accept a longer journey if it offered reliable credit, safe lodging, known tolls and a large market at the end.

53.27 Monsoon, flood and low-water seasons reorganized commercial geography

The same rivers that enabled bulk transport could also disrupt it. Floods altered channels and damaged roads; low water constrained boat drafts; monsoon currents changed travel time and risk. North Bihar's floodplain conditions were particularly important for the approach to Tirhut and Nepal. Trade therefore had a calendar. Seasonal variation influenced when grain, saltpetre, textiles or Himalayan goods could move efficiently, and it created demand for storage so merchants could wait for a better river or market season.

53.28 The eighteenth century changed the political setting without destroying the network

Mughal imperial authority weakened, Bengal's nawabi regime acquired greater autonomy, European companies expanded their commercial power and Patna's political context changed. Yet the basic value of the Ganga corridor and the northward connection to Nepal persisted. Kumkum Chatterjee's study of Bihar between 1733 and 1820 shows merchant activity adapting to political transition rather than simply collapsing. This continuity is important for the transition to Chapters 54–57: colonial economic

transformation worked through older commercial nodes, merchant groups and commodity chains even as it altered their terms.

53.29 Method: each source must remain inside its own chronological box

Trade history is especially vulnerable to retrospective projection because routes often persist and later surveys are much more detailed than earlier evidence. The proper method is comparative but not conflationary. Fitch and Mundy establish late-sixteenth- and early-seventeenth-century movement; company and regional records document seventeenth- and eighteenth-century commodities and institutions; Kirkpatrick-era evidence illuminates late-eighteenth-century Nepal relations; Buchanan-Hamilton gives detailed early-nineteenth-century routes and commodity lists. Later precision may suggest questions for earlier periods, but it does not automatically answer them.

Figure 211 — Evidence firewall for reconstructing interregional trade

53.30 Conclusion: the connected region functioned through circulation

Between Bengal, Bihar, the upper Gangetic plain and Nepal, the economy of Mithila, Vajji and Anga was shaped by circulation as much as by production. The Ganga served as an east–west trunk; Hajipur and Tirhut fed northward routes; Munger and Bhagalpur anchored the Anga stretch; Patna concentrated storage, credit, brokerage and redistribution. Goods moved in both directions, and merchants of many communities operated across political boundaries. The resulting commercial world was neither a closed regional economy nor a colonial creation. It was an early-modern network later reworked—rather than invented—by Company expansion.

Table 53.1 — Evidence domains for reconstructing interregional trade

Evidence domain	What it can establish	Principal limit
Travel narratives: Fitch, Mundy, Tavernier, Bernier	dated routes, merchants, transport, selected commodities and market observations	selective outsider observations; not systematic trade statistics
Company and merchant records	factories, purchases, prices, advances, saltpetre/textile/opium procurement, river export	corporate interests overrepresent commodities profitable to the companies
Regional route reconstructions and sarai evidence	road and river corridors, halts, ferries, transshipment and commercial infrastructure	routes could vary by season, security and political conditions
Kirkpatrick and Buchanan-Hamilton on Nepal	late-18th/early-19th-century Patna–Kathmandu links and commodity directions	later evidence cannot automatically prove 17th-century volumes or identical commodity mixes
Later district trade estimates	mature entrepôt structure, hinterland supply and two-way staple movement	useful for continuity questions, not a substitute for earlier evidence

Chapter 54 — East India Company Expansion and the Remaking of Agrarian Relations

Between the military victories of the East India Company in the 1750s and 1760s and the Permanent Settlement of 1793 lay nearly three decades of experimentation. The decisive change was not that a wholly new agrarian order appeared overnight after Plassey or Buxar. Rather, a commercial corporation acquired political leverage, then fiscal sovereignty, and gradually inserted its own supervisors, councils, collectors, auctions, revenue farmers, courts and accounting practices into an older Mughal–Nawabi system of zamindars, amils, qanungos, patwaris and village producers. Bihar is especially revealing because the transition can be seen through Shitab Rai's revenue administration, the Patna Revenue Council, early experiments in Tirhut, the Rajmahal–Bhagalpur supervisory system and the uneven fiscal geography of Monghyr. This chapter follows that transition from 1757 to the eve of the Permanent Settlement. It therefore stops short of treating the 1793 settlement itself in detail; that belongs to Chapter 55.

54.1 Company expansion was a sequence, not a single conquest

The remaking of agrarian relations began before the Company directly collected land revenue. Plassey in 1757 enlarged Company influence at the Bengal court, but it did not transfer the countryside into a British administrative system. The Battle of Buxar in 1764 was more consequential for Bihar because Company forces defeated a coalition that included Mir Qasim, Shuja-ud-Daula of Awadh and the Mughal emperor Shah Alam II. Even then, military victory had to be converted into fiscal authority, administrative routines and enforceable claims over local intermediaries. The agrarian transition was therefore cumulative: war altered sovereignty; treaties redistributed rights; revenue institutions changed more slowly.

54.2 Buxar made Bihar central to the Company's territorial state

Buxar linked Bihar's political history directly to the making of Company rule. Mir Qasim had earlier shifted his capital to Monghyr and attempted to strengthen nawabi authority against Company interference. His defeat removed a major regional challenge. The settlement that followed brought the Company into a new relationship with the Mughal emperor and the Bengal nawab. From this point Bihar was not merely a corridor for Company trade or military movement. Its land revenue became part of the fiscal foundation of a territorial regime whose military and commercial ambitions increasingly depended on collections from the countryside.

54.3 The Diwani grant of 1765 changed the legal claim to revenue

On 12 August 1765 Shah Alam II granted the Company the Diwani of Bengal, Bihar and Orissa. Diwani signified the right and responsibility to administer the revenues. The grant did not instantly create a European bureaucracy in every pargana. It gave the Company a superior fiscal title while much of the existing machinery remained Indian. This distinction matters. A sanad could transfer sovereignty over revenue without replacing the personnel, village records, customary claims and negotiation through which revenue was actually realised. Agrarian change therefore began as an overlay: a new claimant to surplus stood above older layers of administration.

Figure 212 — From military leverage to direct revenue government, 1757–1793

54.4 “Dual government” describes divided responsibility but can conceal continuity

The years 1765–1772 are often described as a “Dual Government,” with the Company controlling revenue while the nawab retained the nizamat or civil and criminal administration. The phrase captures an important division of formal responsibility, yet newer scholarship warns against imagining two neatly separate machines. Company authority worked through Mughal–Nawabi offices and Indian fiscal agents, while those agents adjusted to Company supervision. Abdul Majed Khan’s study of Muhammad Reza Khan emphasizes continuity and overlap. For Bihar, the role of Shitab Rai similarly shows that the Company initially depended on established expertise rather than governing the countryside through a fully European hierarchy.

54.5 Shitab Rai embodied continuity in Bihar’s early Company revenue system

After the Diwani, Raja Shitab Rai remained a crucial figure in Bihar’s revenue administration under Company supervision. His position illustrates the early logic of indirect control: the Company wanted the fiscal benefits of sovereignty without immediately constructing a costly district bureaucracy. Existing officers knew pargana accounts, landed families, cesses, arrears and local bargaining conventions. Yet this arrangement also created ambiguity about responsibility. Company officials increasingly demanded higher, more regular remittances while local officers remained the visible face of collection. Complaints of corruption or oppression could therefore be directed downward even when the fiscal pressure originated at a higher level.

54.6 Revenue became inseparable from the Company’s fiscal-military needs

The Company was simultaneously merchant, army employer and territorial revenue claimant. Land revenue could finance troops, administration and the purchase of export goods. This altered the political economy of collection. Under an Indian court, revenue also sustained armies and elites, but the Company’s corporate accounts linked territorial surplus to commercial remittance and shareholder expectations in a distinctive way. Contemporary debates repeatedly returned to the expected “surplus” of Bengal and Bihar.

The pressure to know, assess and regularise the countryside was therefore not merely an administrative preference; it was tied to the financial architecture of Company expansion.

54.7 Commercial privilege and fiscal sovereignty reinforced each other

The Company had entered eastern India as a trading corporation. Once it obtained Diwani authority, its commercial and territorial roles became intertwined. Control of customs disputes, saltpetre and opium procurement, advances to producers and the financing of Company investments interacted with land-revenue flows. The precise impact varied by commodity and district, but the structural point is clear: the same institution that claimed public revenue also possessed powerful private and corporate commercial interests. This dual position affected bargaining with merchants, zamindars and officials and helped transform the balance of power within regional markets.

54.8 The 1769 supervisors marked a first attempt to see inside the districts

By 1769 the Company had become dissatisfied with indirect fiscal management and appointed European “Supervisors.” Their mandate was broader than simply checking cash receipts. They were to investigate the history and productive capacity of districts, existing demands on cultivators, collection practices, commerce and justice. In practice they remained dependent on interpreters, Indian clerks and local revenue knowledge. Yet the office signalled a new administrative ambition: to turn the countryside into an object of systematic information. Surveying revenue relations became a technique of rule even before the Company possessed the staff to control them directly.

Figure 213 — Agrarian mediation before and during the Company transition

54.9 The Patna Revenue Council brought Bihar under a new supervisory centre

In 1770 a Revenue Council was established at Patna for Bihar. This was a significant institutional step because it created a provincial node through which Company servants could supervise the older revenue machinery. The council did not eliminate dependence on Indian agents, but it concentrated correspondence and review. Patna’s older role as administrative and commercial centre now acquired a specifically colonial fiscal function. The shift also helps explain why later district histories of Tirhut, Saran and other parts of north Bihar repeatedly refer to orders and supervision emanating from Patna during the transitional years.

54.10 Tirhut reveals how experimental the early district system was

The administrative history preserved for Tirhut is unusually revealing. European supervision appeared after 1769; in 1771 a European Collector was appointed in Tirhut, but the experiment did not last. In 1772 control shifted again under the Provincial Council at Patna and the new five-year revenue settlement. Later annual settlements also proved unstable, and direct European collectorship was restored in 1782. Such reversals show that the Company did not arrive with a finished district system. It tested competing arrangements because it did not yet know how to convert nominal assessments into reliable revenue without destroying the local structures on which collection depended.

54.11 Bhagalpur shows both information failure and fiscal leakage

The Bhagalpur–Rajmahal corridor followed a different sequence. An English Supervisor based at Rajmahal was appointed at the end of 1769. Later district records state that when the Company assumed direct revenue management in 1772, substantial sums from Bhagalpur, Colgong and Chhai were found to have been unaccounted for over preceding years. Whatever the exact mechanisms, the episode demonstrates why Company officials increasingly equated better knowledge with higher revenue security. It also shows the weakness of treating the 1765 Diwani as equivalent to effective local control: legal entitlement and actual remittance could be far apart.

54.12 Monghyr and Anga exposed the limits of paper sovereignty

The Mughal sarkar of Monghyr covered a large and uneven territory, including areas where Company control was weak and some zamindars remained difficult to subordinate. Later revenue analysis described portions as refractory or imperfectly explored. This should not be read as evidence of an empty administrative space; rather, it indicates that claims made in imperial revenue lists exceeded the practical reach of successive states. Company expansion in the Anga zone therefore required negotiation, coercion and new information. A uniform fiscal policy encountered riverine lowlands, forest-edge tracts, zamindari strongholds and shifting jurisdictional boundaries.

54.13 The famine of 1770 was a severe test of the transitional regime

The famine of 1770 belongs to the fuller history of scarcity in Chapter 58, but it cannot be omitted from the remaking of agrarian relations. Contemporary and later district records from Bihar describe crop failure, distress, ruined zamindars and impoverished raiyats. The crisis exposed the dangers of rigid revenue expectations when agricultural output collapsed. It also sharpened debates over responsibility: who should remit, reduce or enforce collections, and who possessed reliable information about local conditions? The famine did not by itself create later revenue policy, but it revealed the human and fiscal costs of governing through imperfect knowledge and competing authorities.

54.14 In 1772 the Company decided to “stand forth as Diwan”

Orders from the Court of Directors instructed the Bengal government to take the entire care and management of revenue into Company hands. Warren Hastings implemented the change in 1772. The revenue headquarters were shifted toward Calcutta, supervisors were redesignated as Collectors, and a Committee of Circuit travelled through districts to make settlements. This was a major constitutional and administrative step. The Company ceased pretending that Indian deputies alone were responsible for fiscal outcomes and made its own servants visibly accountable for revenue management, even though those servants still depended heavily on Indian record-keepers and intermediaries.

54.15 The Committee of Circuit turned assessment into a travelling inquiry

The Committee of Circuit was designed to inspect districts and settle their revenues on the spot. Its work combined inquiry, negotiation and fiscal ambition. Officials sought to discover the “real” resources of estates and parganas, but the information available to them came through interested parties: zamindars, amils, bankers, farmers, clerks and cultivators. The result was not a neutral measurement of agricultural capacity. It was a contest over knowledge. Every estimate of assets and cultivation could affect who obtained a farm, what assessment was imposed and which claims were recognised.

54.16 The quinquennial settlement changed the incentives of collection

The five-year settlement of 1772–1777 frequently awarded revenue farms to the highest bidders. In theory competition would reveal the true fiscal capacity of an estate and secure a predictable payment to government. In practice speculative bids could exceed what cultivation and rents could sustain. Some old zamindars retained their areas by bidding; others were displaced by revenue farmers or agents backed by commercial capital. When a farmer’s contractual obligation was fixed at an unrealistic level, the incentive was to extract quickly from subordinate landholders and raiyats or to default and abandon the farm.

54.17 Zamindars were neither simply abolished nor already modern landlords

The transitional decades are easily distorted by later legal categories. Zamindars before 1793 possessed important hereditary, fiscal and political claims, but the Company had not yet defined them as the kind of proprietary landlords created by the Permanent Settlement. Under the 1772 experiment, some were bypassed in favour of revenue farmers; others acted as farmers themselves; dispossessed zamindars could receive allowances. Their position was therefore unstable. The crucial question was not whether they were “owners” in a modern sense, but what bundle of collection rights, local authority and hereditary claims the state would recognise.

54.18 Raiyats faced changing collectors more quickly than changing cultivation

For cultivators, the most immediate changes were often not new crops or technologies but new layers of demand and uncertainty. A raiyat might encounter the same village headmen and patwari while the person entitled to collect above them changed from a zamindar to a revenue farmer or khas manager. Short leases encouraged some intermediaries to prioritise immediate extraction over long-term cultivation. At the same time, cultivators were not passive. They could conceal assets, move, negotiate, resist illegal cesses, appeal to officials or exploit rivalry among collectors. Agrarian relations remained a field of bargaining, though the Company increasingly sought to discipline that bargaining through written engagements.

54.19 Indian fiscal expertise remained indispensable

The language of “direct” Company management can mislead if it suggests that European Collectors themselves knew every field, rent roll and customary due. Qanungos preserved fiscal precedents and local records; patwaris maintained village accounts; amils and diwans understood collection routines; bankers advanced funds and transmitted remittances. European officials depended on these actors to translate both language and institutions. The transition therefore produced hybrid administration. Colonial power lay increasingly in appointment, review, coercion and audit, while much everyday knowledge continued to be generated by Indian personnel.

54.20 Arrears linked fiscal pressure to credit and coercion

Revenue was due on a schedule even when harvests, prices and local collection were uncertain. This made arrears a central problem. Zamindars and farmers borrowed to meet instalments; bankers and moneyed intermediaries became important in the fiscal chain; failure could lead to removal, confinement, khas management or reassignment. At lower levels, attempts to recover arrears could be passed onto raiyats through enhanced rents and cesses. The Company thus transformed agrarian relations partly by making punctual remittance to a distant treasury a dominant test of administrative success.

54.21 The failure of the five-year experiment led to shorter settlements

The quinquennial settlement produced defaults, complaints and administrative criticism. When it expired, the Company moved toward annual or short-term settlements, sometimes with zamindars and sometimes with farmers. Tirhut's later administrative history records annual settlements from the late 1770s into the 1780s. Shorter terms reduced the government's exposure to a bad long contract but created another problem: uncertainty for those managing estates. The search for reliable revenue thus oscillated between flexibility and stability, with no consensus yet on the correct duration or on the proper person with whom government should settle.

54.22 Tirhut's restored collectorship in 1782 shows continuing uncertainty

The restoration of a European Collector in Tirhut in 1782, with François Grand among the early office-holders, demonstrates that the Company was still redesigning its administrative map well after the 1772 reforms. The Collector had to determine assessments, enforce payments and work through local intermediaries across a large and ecologically varied region. Difficulties of realisation remained significant. The episode matters because later colonial districts can look retrospectively inevitable; in the 1780s they were experimental institutions whose authority, staffing and territorial reach were still being negotiated.

Figure 214 — Regional administrative transition in Tirhut, Bhagalpur–Rajmahal and Monghyr

54.23 Bhagalpur's collectorate linked fiscal administration to frontier governance

Bhagalpur's early Company administration developed at the meeting point of Ganga commerce, settled agrarian zones and hill-frontier politics. A separate collectorate emerged during the late 1770s, with Augustus

Cleveland becoming a prominent Collector from 1779. His later reputation is associated especially with relations with hill communities, but for agrarian history the important point is institutional: revenue, policing, frontier negotiation and district knowledge were becoming concentrated in the Collector's office. The colonial district was not merely a tax jurisdiction; it was becoming an integrated territorial apparatus.

54.24 Revenue experiments altered local political competition

Auctions and short settlements created openings for men with cash, credit and official connections to compete with hereditary landed families. Some bidders were substantial merchants or banians; others were agents acting behind nominal farmers. Old zamindars in turn used kinship, armed followings, petitions and local influence to defend their positions. Company revenue policy therefore redistributed opportunities within rural elites even before 1793. The result was not simply the rise of one new class, but intensified competition among hereditary landholders, revenue entrepreneurs, bankers, officials and village-level controllers.

54.25 Revenue administration and justice became increasingly entangled

The Company's fiscal authority generated disputes over possession, rent, arrears, cesses and succession. During the transitional period the boundary between revenue and judicial business was unstable. Supervisors and Collectors handled complaints while provincial councils and newly reorganised courts altered channels of appeal. This mattered socially because the forum in which a dispute was heard could shape whose records and testimony were decisive. The Company's attempt to separate and regularise judicial functions was therefore also part of agrarian transformation: land relations became progressively more textual, litigable and reviewable by colonial institutions.

54.26 The production of records was itself a form of agrarian intervention

The new regime demanded histories of districts, lists of estates, accounts of produce, customary cesses, rent rolls, boundaries and arrears. These records were not merely descriptive. Once entered into a Collector's register or settlement paper, a claim could acquire new administrative weight. Conversely, rights that were customary but poorly documented could become vulnerable. The Company's growing archive therefore helped transform fluid relationships into categories legible to government. Later colonial surveys would intensify this process, but its roots are visible in the supervisory and settlement experiments of the 1760s–1780s.

54.27 Territorial revenue financed an expanding colonial political economy

Land revenue did not remain inside the district from which it was collected. It entered a wider Company system that supported civil establishments, armies, debt service and commercial investments. This changed the scale at which agrarian surplus was mobilised. Bihar's cultivators and landed intermediaries were connected through the treasury to military campaigns and export procurement far beyond Bihar. The relationship between village production and imperial finance thus became more direct, even though the actual path of money still passed through many intermediaries and often depended on merchant credit.

54.28 By the 1780s the problem was no longer whether to rule, but how

The experiments since 1765 convinced Company officials that they could not simply collect revenue through inherited arrangements without defining their own administrative principles. Yet they disagreed sharply about the solution. Should revenue be farmed competitively? Should hereditary zamindars be

preferred? How should productive capacity be estimated? What term would encourage improvement without sacrificing state income? Debates involving officials such as Philip Francis, John Shore and later Cornwallis turned local difficulties into theories of property and political economy. The countryside of Bengal and Bihar became the testing ground for a colonial doctrine of agrarian governance.

54.29 The decennial settlement was an endpoint of experimentation, not yet the Permanent Settlement

By the late 1780s Company policy moved toward longer settlements and greater reliance on zamindars. The Decennial Settlement beginning in 1789 represented an attempt to stabilise assessments and landed authority after two decades of short-term changes. It became the immediate institutional bridge to the Permanent Settlement of 1793. Yet the two should not be collapsed. At the moment of decennial settlement the permanence of the arrangement was still a policy question. Chapter 55 therefore begins where this chapter ends: with the conversion of a decade-long settlement into a perpetual one and the new legal architecture of landed property.

Figure 215 — Evidence firewall for the Company transition

54.30 Conclusion: Company rule remade agrarian relations through institutions before it fixed property law

Between 1757 and 1793 the East India Company transformed from a privileged merchant into the principal territorial revenue authority of Bengal and Bihar. In Mithila, Vajji and Anga this transition appeared through Patna's revenue councils, Tirhut's shifting collectorates, Rajmahal–Bhagalpur supervision, the uneven fiscal geography of Monghyr, revenue farms, annual settlements, expanding archives and new channels of appeal. Much older personnel and practice survived, but they operated under changing incentives and a new sovereign claimant. The Permanent Settlement did not create colonial agrarian relations from nothing; it attempted to freeze and legalise a field already profoundly reorganised by three decades of fiscal experiment.

Table 54.1 — Administrative phases in the remaking of agrarian relations, 1757–1793

Phase	Administrative arrangement	Agrarian significance
-------	----------------------------	-----------------------

Phase	Administrative arrangement	Agrarian significance
1757–1765	Company political and military leverage without general Diwani	older revenue institutions continue; Company influence expands before direct fiscal sovereignty
1765–1769	Diwani with revenue collection largely through Indian officers	new sovereign claimant overlays existing zamindars, amils, qanungos and village records
1769–1772	European Supervisors; Patna Revenue Council; early district experiments	systematic information gathering and closer Company oversight enter the countryside
1772–1777	Company “stands forth as Diwan”; Committee of Circuit; quinquennial revenue farming	competitive farms and written engagements destabilise some hereditary intermediaries and intensify short-term extraction incentives
1777–1789	annual / short settlements; changing councils and collectors	continued experimentation with zamindars, farmers, khas management and district offices
1789–1793	Decennial Settlement and debate over permanence	attempt to stabilise landed authority and assessment; immediate bridge to Chapter 55’s Permanent Settlement

Chapter 55 — Permanent Settlement and Landed Society

The Permanent Settlement of 1793 converted the experimental decennial settlement of Bengal and Bihar into a perpetual state demand upon designated zamindars, independent talukdars and other proprietors. Its importance lay not simply in fixing revenue, but in reworking the legal language of landed authority. A hereditary revenue-collecting right was increasingly treated as proprietary property, while punctual payment to the colonial state became the condition of security. Yet the settlement did not define every right below the zamindar. Raiyats, under-tenure holders, village officials, service tenures, rent-free grants and customary users continued to inhabit a layered agrarian field that subsequent regulations, courts and tenancy statutes tried to order. In Mithila, Vajji and Anga the effects were regionally uneven: Tirhut entered a large permanent settlement in 1793, Bhagalpur was only partially settled at that date, and Monghyr contained a mixture of estate forms and difficult fiscal geographies. This chapter therefore studies the Permanent Settlement as the beginning of a new landed society, not as a one-day replacement of all older agrarian relations.

55.1 From decennial experiment to perpetual settlement

The decennial settlement of 1790–91 was initially framed as a ten-year arrangement. Cornwallis and his colleagues then chose to make the assessed demand perpetual in 1793. The change mattered because future agricultural expansion and rental growth would accrue chiefly below the state's fixed demand. In return, the Company expected secure landed property and predictable revenue to encourage improvement. The settlement therefore joined fiscal calculation to a political theory of property. It was less an isolated regulation than the culmination of the experiments traced in Chapter 54.

55.2 What Regulation I of 1793 actually fixed

Regulation I of 1793 declared the public assessment on settled estates fixed in perpetuity. It did not freeze the actual produce of the land, the number of cultivators, the rent collected from each raiyat, or the internal structure of every estate. The distinction between public jama and estate income is fundamental. A permanently fixed state demand could coexist with changing cultivation, prices, rents and subordinate tenures. Much later agrarian conflict arose precisely within that widening space between fixed public revenue and variable private rental income.

Figure 216 — Permanent Settlement: what was fixed, and what remained contested

55.3 Zamindar as proprietor: a colonial legal translation

Colonial law increasingly described the zamindar as proprietor. This was not merely a neutral translation of an unchanged Mughal category. Earlier zamindari authority had combined revenue collection, local political influence, hereditary claims, jurisdictional habits and negotiated relations with superior power. The Permanent Settlement selected and hardened one aspect—responsibility for the assessed revenue—and linked it to a stronger language of transferable property. The result was a legal simplification of a socially complex office.

55.4 Property rights were tied to revenue responsibility

The new proprietary language came with a hard condition: the estate stood as security for the government demand. Failure to pay arrears could expose all or part of the estate to public sale. Property therefore became more alienable but also more vulnerable to fiscal default. The same arrangement that promised hereditary security also created a mechanism through which old families could lose estates and purchasers could acquire them. Stability and dispossession were built into the same legal architecture.

55.5 The state demand was fixed, rural rents were not

Because the state demand was fixed, an estate that expanded cultivation or raised rents could retain more of the increase. This incentive lay at the heart of the official theory of improvement. Yet the state did not guarantee that gains would come from investment rather than rent enhancement, new cesses, closer measurement or pressure on tenants. The settlement thus created a structural incentive to increase net rental income without specifying a single path by which landlords should do so.

55.6 Raiyats were not made simple tenants by a single clause

Raiyats were essential cultivators and revenue-producing subjects, but the Permanent Settlement did not settle their rights with the same clarity given to the state's claim against proprietors. Existing customs, rent rates, occupancy practices and written pattas continued to matter. Later regulations and nineteenth-century

rent legislation repeatedly returned to questions of occupancy, enhancement, eviction and receipts. Those later laws are evidence that 1793 left the landlord–cultivator relationship incompletely defined.

55.7 Custom, contract and coercion beneath the settlement

Below formal regulations lay village practice. Rent could be shaped by crop, soil, irrigation, flood risk, market access, customary service and local bargaining. Zamindars acted through amlas, tahsildars and other agents; raiyats could resist, conceal, litigate, migrate or negotiate. The Permanent Settlement altered the framework within which these relations operated, but it did not abolish the social power embedded in local knowledge, credit and control over records.

55.8 Revenue sale made property conditional on punctuality

Revenue-sale procedure gave the government a powerful enforcement mechanism. Later statutes refined the precise rules, but the principle was already central: an estate in arrears could be sold and the purchaser could obtain a new legal position under the fixed assessment. The sale regime turned punctual fiscal payment into a recurring discipline on proprietors. It also encouraged litigation over shares, encumbrances and subordinate interests, making the courthouse part of rural political economy.

55.9 Estate transfer created a market in fiscal rights

Permanent settlement made landed interests more legible as transferable assets. Estates and shares could pass through inheritance, partition, private transfer, court decree or revenue sale. Buyers might include older landed families, merchants, officials or creditors. This did not create a perfectly liquid market in land, but it widened the circumstances in which revenue-paying rights could circulate beyond inherited political lineages. Landed society became increasingly intertwined with money, debt and legal title.

55.10 The settlement did not abolish intermediaries

The image of a state, a zamindar and a mass of tenants is too simple. Existing talukdars, tenure-holders, village headmen, service grantees and rent-free interests did not vanish. New under-tenures also appeared. The agrarian order became vertically layered, with multiple claims to rent and multiple levels of responsibility. Later Bihar land-reform legislation would still describe an intricate hierarchy of intermediaries, showing how durable this layered structure became.

Figure 217 — Layered hierarchy of landed claims under permanent settlement

55.11 Subinfeudation and the growth of layered tenures

Subinfeudation allowed estate proprietors to create subordinate rent-receiving interests, sometimes for fixed payments and long terms. Such arrangements could mobilise capital, delegate management and shift risk downward. They could also separate the person ultimately liable for government revenue from those who actually supervised cultivation or collected rent. The result was not uniform absenteeism but a spectrum of estate-management forms, from direct control to multiple tiers of intermediaries.

55.12 Patni tenure belongs to the later evolution of the system

Patni taluks are important but chronologically later than 1793. Regulation VIII of 1819 recognized and regulated such perpetual under-tenures, reflecting practices that had developed under the freedom of proprietors to lease their lands. The patni system illustrates how the Permanent Settlement generated institutional consequences over time. It should therefore be treated as an evolution within the permanently settled order, not as a tenure fully specified in the original 1793 settlement.

55.13 Inheritance and partition multiplied landed interests

Inheritance could fragment estates or shares, while family strategies could also preserve large domains through impartibility claims, trusts or managerial arrangements. Regulation XI of 1793 dealt with inheritance to revenue-paying land according to applicable personal law, but actual succession could produce litigation and partition. In Tirhut especially, later records show a dramatic multiplication of revenue-paying estates through partitions and resumptions. A fixed revenue regime did not mean a fixed map of ownership.

55.14 Tirhut entered the settlement as a large but incomplete fiscal landscape

The Tirhut settlement illustrates both scale and incompleteness. Gazetteer evidence records a substantial area assessed at the decennial settlement and made permanent in 1793, while large areas remained outside the original assessment and were later brought onto the revenue roll through resumption proceedings. The apparent neatness of a permanent settlement therefore concealed an unfinished fiscal geography. Subsequent surveys, partitions and resumptions continued to remake the landed map.

55.15 Darbhanga Raj: political authority narrowed into zamindari property

The Darbhanga Raj demonstrates how permanent settlement could narrow an older regional authority into a colonial category of landed property. Later legal records concerning the Raj show that not all jagir villages were included in the settlement and that the family's older rights could be reduced to specified dues in excluded tracts. The surviving estate remained formidable, but its relationship to government was increasingly that of a large revenue-paying zamindari rather than an autonomous territorial principality.

55.16 Revenue-free and disputed lands remained a major frontier

Revenue-free grants, jagirs, lakhraj lands and other exemptions posed a basic problem: what land properly belonged within the taxable estate? The 1793 regulatory framework was accompanied by rules concerning revenue-free lands, but disputes endured. Claims to old grants required proof; invalid or unsupported exemptions could later be resumed and assessed. The permanently settled landscape was therefore bounded by a continuing documentary struggle over what counted as valid exemption.

55.17 Resumption proceedings altered the settled map

Nineteenth-century resumption proceedings altered the fiscal map without overturning the principle of permanent assessment. Lands judged improperly exempt could be assessed and brought into the revenue system, often at later dates. In north Bihar such proceedings added very large areas and revenue to the roll. This is a reminder that "Permanent Settlement" referred to the permanence of an assessment once validly fixed, not to a guarantee that every parcel had already been identified and settled in 1793.

55.18 Bhagalpur shows why 1793 was not locally simultaneous

Bhagalpur is a particularly useful corrective to textbook generalization. District evidence indicates that only a modest revenue total was permanently settled there in 1793 and that much larger sums were permanently settled in subsequent decades. The eastern zone therefore entered the regime through a more extended chronology. Anga's social history cannot be reconstructed by assuming that every estate in the Bhagalpur region acquired its permanent status on the same day as major Tirhut estates.

55.19 Monghyr and Anga retained mixed tenurial geographies

Monghyr likewise contained diverse landed formations. Older zamindaris, service-linked holdings, difficult frontier tracts and imperfectly assessed areas complicate any picture of a uniform proprietary countryside. The Permanent Settlement supplied a legal-fiscal framework, but the degree to which it mapped directly onto village-level authority varied. Regional political history and local tenure remained necessary to understand who actually controlled rent, labour and access to land.

Figure 218 — Regional settlement profiles in Tirhut/Darbhanga, Bhagalpur and Monghyr/Anga

55.20 Service tenures complicate a simple landlord–tenant model

Service tenures are especially important in the Anga–Monghyr–Bhagalpur zone. Ghatwali and related holdings could combine land with obligations of policing, guarding passes or maintaining routes. Later legal disputes often turned on whether such lands were included in a permanently settled zamindari or independently resumable. These cases show that agrarian property could carry public or quasi-public obligations and cannot always be reduced to a simple private landlord–tenant relationship.

55.21 Landed elites diversified their strategies

Landed elites responded to the new regime through management, leasing, borrowing, litigation, purchase and political alliance. Some consolidated large estates; others lost shares to arrears or debt. Merchants and moneyed groups could enter the landed sphere, while established families could use credit and legal expertise to survive. Permanent settlement thus linked rural hierarchy to expanding legal and financial networks rather than isolating the countryside from commercial society.

55.22 Courts and documentation became instruments of landed power

Written title, account books, rent rolls, receipts, decrees and registration became increasingly important resources. Estate offices accumulated paper; courts demanded documentary proof; collectors maintained registers. Those who controlled records gained strategic advantages in disputes over rent, tenure and inheritance. The archive was therefore not merely a neutral source for historians. It was itself one of the technologies through which colonial landed power was made and contested.

55.23 Rent enhancement became the central unresolved question

With the public revenue fixed, disputes over rent became the central distributive conflict of the system. Landlords sought to capture agricultural and market growth; cultivators defended customary or contractual rates. The law struggled to distinguish legitimate enhancement from arbitrary exaction. The Bengal Rent Act of 1859 and later Bihar tenancy legislation addressed problems that had accumulated under permanent settlement, including occupancy rights, pattas, enhancement and eviction.

55.24 Cash rents, produce rents and ecological variation

Not all rents were cash rents, and ecological diversity mattered. Produce-sharing arrangements survived in many places, particularly for less secure tenants or particular crops and localities. Flood-prone plains, riverine chars, wet rice zones and market-oriented tracts generated different bargaining conditions. A permanently fixed state demand sat above an agrarian economy whose rents could be expressed in money, produce or mixed obligations and whose risks remained highly local.

55.25 Peasant differentiation persisted beneath zamindari society

Rural society was differentiated among substantial raiyats, small holders, under-raiyats, sharecroppers, labourers and service groups. The Permanent Settlement did not create these differences from nothing, nor did it erase them. By placing a legally strengthened rent-receiving layer above cultivators, however, it reshaped the channels through which surplus was claimed. Later surveys reveal both occupancy rights among many raiyats and continuing insecurity among others.

55.26 Women, inheritance and landed property

Women could inherit, manage or litigate over revenue-paying property under applicable personal laws, but formal title did not erase gendered constraints on possession and management. Regulation XI of 1793 recognized inheritance questions rather than establishing a gender-neutral property regime. Widows and female estate-holders appear in later litigation, often through guardians, managers or courts. Their presence demonstrates that landed society cannot be described solely through male zamindars, even though patriarchal institutions remained powerful.

55.27 Famine, flood and arrears tested the fixed-demand principle

A fixed government demand shifted weather and production risk downward. Flood, drought, crop failure or price disruption did not automatically reduce the state's claim. Proprietors facing arrears might borrow, squeeze collections, sell assets or risk revenue sale; cultivators could face rent pressure at precisely the moment production fell. Yet remission and administrative discretion did not vanish entirely. The key structural point is that permanence reduced the routine possibility of reassessing the state demand according to annual output.

55.28 Later rent law reveals what 1793 left unresolved

The Bengal Rent Act of 1859, later revenue-sale law and the Bihar Tenancy Act of 1885 should be read as evidence of unresolved tensions within permanently settled society. They progressively defined occupancy, enhancement, receipts, under-tenures and sale protections. These statutes did not merely add detail to a complete 1793 design. They were attempts to govern conflicts that the original settlement had left to custom, contract, landlord power and judicial interpretation.

Figure 219 — Chronology firewall: 1793 and later consequences

55.29 Long-term consequences without monocausal explanation

Permanent settlement had major consequences, but it should not be made a single cause of every later agrarian inequality. Ecology, population, commodity markets, credit, caste and community organization, estate-management choices, colonial courts, transport and political change all mattered. The settlement created a durable fiscal-property framework within which these forces operated. Its historical importance lies in the way it structured incentives and legal claims over generations, not in a mechanically uniform effect everywhere.

55.30 Conclusion: a fixed state demand created a changing landed society

The Permanent Settlement fixed the colonial state's revenue claim while leaving landed society itself dynamic. Zamindars gained stronger proprietary recognition but faced sale for default. Estates fragmented, transferred and generated under-tenures. Raiyats retained and contested customary claims that later law had to define more explicitly. Tirhut, Darbhanga, Bhagalpur and Monghyr followed different local paths into the same broad regime. The result was not a frozen countryside but a changing hierarchy of property, rent, credit, documentation and cultivation. Chapter 56 turns from this landed framework to one of its most consequential commercial pressures: indigo and contract agriculture.

Table 55.1 — Institutions and longer consequences of permanently settled landed society

Institution / rule	Immediate function	Longer agrarian consequence
Permanent Settlement, 1793	Fix public revenue demand with recognized proprietors	stronger transferable estate property but continued conflict over subordinate rights
Revenue sale principle	Enforce punctual payment through sale for arrears	estate transfer and greater connection between land, debt and auction
Under-tenures	Allow proprietors to lease and delegate rent collection	layered intermediary interests and separation of ownership from direct management
Inheritance / partition	Transmit revenue-paying property under applicable law	fragmentation of shares and multiplication of estates

Institution / rule	Immediate function	Longer agrarian consequence
Rent legislation, 1859 onward	Regulate pattas, occupancy, enhancement and eviction	partial legal definition of raiyat rights left unresolved in 1793
Bihar Tenancy Act, 1885	Systematize landlord–tenant categories and occupancy rules	mature legal architecture of permanently settled agrarian society

Chapter 56 — Indigo and Commercial Agriculture

Indigo was one of the clearest ways in which colonial commercial agriculture entered the agrarian society created under permanent settlement. The crop linked cultivators and labourers in Bihar to European capital, Calcutta agency houses, factory processing, long-distance transport and volatile international dye markets. Yet the system was not uniform. Indigo could be grown directly on factory-controlled land, by tenants under advance-and-contract arrangements, or by independent cultivators. North Bihar—especially Tirhut, Darbhanga, Muzaffarpur, Saran and Champaran—became the principal European indigo zone during the nineteenth century, while Bhagalpur and Monghyr also supported significant production. This chapter therefore treats indigo as both a crop and an agrarian institution: it altered land use, credit, labour, rents, contracts and the distribution of risk. It also traces the technological and market crisis created by synthetic indigo after 1897 and the distinct Champaran conflict that culminated in the 1917 inquiry and the Champaran Agrarian Act of 1918.

56.1 Indigo as commodity, dye and agrarian institution

Indigofera plants produced a dye whose value depended on far more than acreage. The crop had to be cut at the correct stage, processed rapidly in vats, oxidized, settled, boiled or pressed and dried into cakes of marketable quality. The commodity therefore joined field cultivation to factory manufacture. A bad crop, delayed cutting, weak fermentation or falling London prices could affect the entire chain. For cultivators the relevant question was different: what land, labour and credit had to be diverted from food production in order to satisfy the factory. Indigo is best understood as a combined agricultural-industrial institution.

56.2 European indigo expansion in eastern India

European-supervised indigo manufacture expanded in eastern India from the late eighteenth century, drawing on export demand, Calcutta commercial finance and the Company state. Early concentration lay in Bengal, but Bihar became increasingly important during the nineteenth century. The chronology should not be simplified into a single founding date for the region. Factories appeared at different times, often through local leases, partnerships and estate connections. By the mid-nineteenth century North Bihar had become a major field for European planting enterprise.

56.3 Capital, agency houses and seasonal finance

Indigo was capital intensive because planters had to finance land rights, vats, buildings, cattle, seed, staff, transport and advances months before sale. Calcutta agency houses and other creditors supplied much of this working capital. The plantation was therefore simultaneously a debtor to commercial finance and a creditor to rural society. Advances to cultivators allowed sowing to begin but also created obligations that could roll from season to season. Credit made the crop possible while also redistributing bargaining power.

56.4 Permanent settlement and access to landed rights

The permanently settled countryside gave European planters opportunities to acquire leases, mortgage interests and other tenurial rights from zamindars and intermediate holders. They did not normally replace the landed hierarchy; they entered it. In some places a factory's economic leverage derived less from ownership of every field than from rights over villages, leases or debts owed by local proprietors. This fusion of commercial capital with layered land rights helps explain why an apparently private crop contract could carry coercive force.

Figure 220 — Indigo as an agricultural, industrial and financial chain

56.5 North Bihar becomes a major plantation zone

By the second half of the nineteenth century the principal European indigo tracts of Bihar lay in Muzaffarpur and Darbhanga within the Tirhut division, and in Saran and Champaran. Scholarship on plantation science describes Bihar as the refuge and later centre of an industry that had contracted in Bengal after the Indigo Revolt. North Bihar's alluvial plains, dense cultivation and extensive tenurial networks gave planters a large cultivator base, but they also ensured that indigo competed directly with peasant food and fodder requirements.

56.6 Floodplains, soils and the geography of the crop

Indigo favoured well-prepared loamy soils and required careful timing in relation to rainfall and moisture. North Bihar's floodplains could be agriculturally productive but environmentally unstable: rivers shifted, drainage varied and annual inundation affected both estate boundaries and crop choices. Indigo therefore did not simply occupy "waste" land. Its profitability depended on selecting suitable upland or better-drained plots, which often were also valuable to cultivators for other crops. Environmental suitability became an agrarian bargaining issue.

56.7 Three broad systems of cultivation

Colonial Bihar sources distinguish several broad methods. Under *nij* or *zerat* cultivation the factory cultivated land under its own control using hired or attached labour. Under *assamiwar* or *ryoti* arrangements tenant cultivators sowed indigo under agreements, often linked to advances and to a factory's tenurial influence. Under *khuski*, cultivators outside the factory's tenurial domain contracted more independently to supply indigo. These categories overlapped in practice, but they reveal different distributions of land control, labour obligation and production risk.

56.8 *Nij* or *zerat* cultivation: direct factory farming

Direct cultivation placed the tasks of ploughing, sowing, weeding and harvesting under the factory's management. It required land, cattle and labour on a scale that could be expensive, but it also gave the planter

greater control over timing and agricultural technique. Darbhanga's early-twentieth-century record is particularly important: the Imperial Gazetteer noted that in the Samastipur subdivision a very large share of the indigo area was cultivated directly by factories. That local pattern should not be generalized to all Bihar.

56.9 Assamiwar or ryoti cultivation: contracts with tenants

Assamiwar or ryoti cultivation shifted much of field labour and crop risk to tenants. A cultivator accepted an advance or agreement and was required to sow designated land. The factory supplied seed or specified practices and later received the crop for processing. Because many planters also held leases or other superior interests over the villages concerned, the contract could be reinforced through rent, tenure and local authority. The legal form of agreement therefore cannot by itself establish how voluntary cultivation was in practice.

56.10 Khuski cultivation and more independent contracting

Khuski cultivation involved contracts with cultivators who were not tenants of the factory. Sources from Champaran describe such agreements as more voluntary because the planter lacked the same tenurial hold over the cultivator. Factories might have to offer better prices or seed and advances to attract the crop. Precisely for that reason, planters often considered khuski less advantageous than arrangements embedded in landlord-tenant relations. The distinction illustrates how commercial agriculture depended upon agrarian power, not just crop profitability.

56.11 Tinkathia was a Champaran-specific contractual regime

Tinkathia should be used with geographical precision. In Champaran it referred to the obligation, under indigo agreements, to devote three kathas out of a bigha—three-twentieths of the holding—to indigo, generally on selected land. Other proportions and arrangements also existed, and other Bihar districts employed different cultivation systems. The later fame of tinkathia through the Champaran movement has sometimes caused it to be projected over the whole indigo economy. This chapter treats it as one regional contract regime.

Figure 221 — Cultivation systems in colonial Bihar

56.12 Advances could bind cultivation to debt

Advances reduced the cultivator's need for cash before sowing but could also bind future production. Accounts might carry balances forward, and disputes arose over rates, deductions, measurement and the price paid for the plant. In a subsistence-sensitive rural economy, a cash advance could be attractive in one season and restrictive in the next. The economic issue was therefore not simply whether money changed hands, but whether the cultivator could realistically refuse renewal, change crop or clear the account on fair terms.

56.13 Contract and coercion existed on a spectrum

Indigo relations ranged from genuinely bargained cultivation to severe coercion. Planter servants, village intermediaries, rent claims, control of leased estates, police access and local influence could all affect a cultivator's capacity to refuse. The 1860 Indigo Commission documented violent and coercive practices in Bengal, while later Bihar records show a different but still unequal plantation structure. It is methodologically safer to identify the specific mechanism—debt, tenure, intimidation, illegal cesses or contractual condition—than to treat every indigo agreement as identical.

56.14 Indigo competed with food crops and household priorities

For cultivators the opportunity cost of indigo was central. Land placed under the dye crop could otherwise produce rice, maize, pulses, oilseeds, tobacco or fodder. Timing also mattered: ploughs, cattle and household labour had to be available when the factory required them. Even when indigo generated cash, the cultivator might regard the payment as inadequate compensation for lost food production, soil preparation or risk. The plantation economy therefore converted a global commodity demand into a local contest over household crop priorities.

56.15 Labour, ploughs and the hidden costs of plantation production

Factories depended on labour well beyond the contracted field. Ploughmen, cattle tenders, cutters, cartmen, vat workers, mechanics, watchmen and clerks connected village agriculture with factory manufacture. Direct-cultivation estates had especially large labour requirements. Some costs were visible as wages; others were embedded in tenant obligations, customary services or pressure on local transport and cattle. A complete history of indigo must therefore include the labour regime around the factory rather than counting only acres sown.

56.16 From green plant to blue cake: factory processing

Once cut, indigo had to reach the factory quickly. Plant material was submerged in steeping vats, where fermentation released the dye precursor. The liquor moved to beating vats and was oxidized so that blue indigo precipitated. The sediment was collected, heated or boiled, pressed and dried into cakes. This manufacturing stage explains the characteristic masonry vats and factory complexes found across old indigo tracts. It also explains why agricultural experimentation and chemical knowledge became increasingly important when international competition intensified.

56.17 River transport, railways and the Calcutta market

Finished indigo cakes moved through a transport hierarchy of carts, river landings, roads and later railways. The Ganga system connected Bihar's inland factories to Patna and Calcutta, while local rivers and roads linked Tirhut, Bhagalpur and Monghyr production zones to the trunk network. Rail expansion

reduced some transport constraints but did not eliminate dependence on seasonal roads and waterways. Commercial agriculture was therefore inseparable from the wider transport transformation already traced in Chapters 53–54.

56.18 Tirhut and Muzaffarpur: a dense factory landscape

Tirhut's nineteenth-century landscape contained numerous factories and outworks, with Muzaffarpur emerging as a major centre of the European planting community. Factory locations followed access to cultivable land, water and transport rather than a single administrative grid. European residence, club life and planter associations created a distinct social world, but production still rested on surrounding Indian villages. The factory compound should therefore be read as a node embedded within a much larger agrarian economy.

56.19 Darbhanga and Samastipur: direct cultivation as a distinctive feature

Darbhanga provides unusually useful evidence for change over time. The Imperial Gazetteer reported that the fall in natural-indigo prices caused factories to abandon or sharply reduce cultivation. In 1903–04 the district still had roughly 34,000 acres under indigo, concentrated especially in Samastipur, while the number of factories was already falling. It also noted the exceptionally high share of direct factory cultivation in Samastipur. These details show that decline did not produce an immediate or uniform disappearance.

56.20 Champaran: planter tenures and agrarian power

Champaran differed because European planters often combined factory enterprise with extensive tenurial rights held from large estates such as Bettiah. This embedded the crop contract within landlord-tenant relations. Assamiwar cultivation and tinkathia became particularly important there, and the transition away from natural indigo after synthetic dye appeared generated new disputes over rents and compensation. The 1917 crisis therefore arose from a long agrarian history, not merely from Gandhi's arrival or from a sudden isolated abuse.

56.21 Bhagalpur: indigo within a diversified commercial economy

Bhagalpur's commercial economy was diversified among grain exports, silk, oilseeds and other manufactures, yet indigo remained significant in the late nineteenth century. The Imperial Gazetteer described it as a principal manufacture and gave an annual output on the order of 125 tons in the period it summarized. This Anga-zone evidence is important because it prevents the history of indigo from being reduced entirely to North Bihar. The crop occupied different proportions of local agriculture but participated in the same export commodity network.

56.22 Monghyr and the Begusarai factory cluster

Monghyr likewise had an important indigo sector. Hunter's 1877 account, repeated in the district gazetteer, estimated about 10,000 acres under indigo and an output of roughly 4,000 maunds, with a concentration of factories in the Begusarai subdivision, including Manjhaul, Begusarai, Bhagwanpur, Begamsarai and Daulatpur. The later administrative geography should not obscure this historical connection: the Begusarai tract then belonged to Monghyr and formed part of the wider Anga-Bihar commercial corridor.

Figure 222 — Regional indigo profiles across Mithila-Vajji-Anga

56.23 Planters, zamindars and layered landed interests

Planters often obtained leases, mortgages or other rights from zamindars and estate managers who themselves needed cash. This relationship could be cooperative, competitive or litigious. A planter might strengthen a landlord through finance while simultaneously gaining control over village rents or crop conditions. The resulting agrarian hierarchy cannot be represented as a simple opposition between European factory and Indian village. Zamindars, tenure-holders, managers, moneylenders, village headmen and raiyats all occupied positions within the commercial chain.

56.24 Petitions, litigation and everyday peasant resistance

Cultivators did not wait for spectacular rebellion to resist. Petitions to magistrates, refusal to sow, disputes over measurements, litigation, evasion, delayed performance and collective village action appear throughout the documentary record. The imbalance of power made such tactics risky, but they demonstrate continuous negotiation. Commercial agriculture was therefore produced through conflict as well as contract. The archival visibility of a major inquiry should not erase the quieter practices through which cultivators tried to limit obligations or improve terms.

56.25 The Indigo Revolt in Bengal and the re-centering of production in Bihar

The Indigo Revolt of 1859–60 was centred in Bengal rather than Bihar, and that distinction matters. The Indigo Commission of 1860 exposed the deep conflicts within Bengal's contract system. In subsequent decades much European indigo enterprise was re-centred in Bihar, where plantations expanded in Muzaffarpur, Darbhanga, Saran and Champaran. This shift did not mean that Bengal's institutional history simply moved west unchanged. Bihar planters adapted to local land tenures, floodplain ecology and labour relations.

56.26 Plantation science and attempts to improve natural indigo

Late-nineteenth-century planters responded to competition by treating indigo increasingly as a scientific crop and chemical product. Experiments addressed seed selection, soil preparation, manures, fermentation,

oxidation and the extraction of a larger proportion of indigotin from the plant. Colonial agricultural scientists examined plantation methods, while planters established experimental routines of their own. Such activity shows that decline was not passive: plantation capital tried to use agronomy and chemistry to defend natural indigo against changing world prices.

56.27 Synthetic indigo after 1897 transformed the market

The decisive market shock came from synthetic indigo, commercially produced in Germany from the late 1890s. It offered a purer and increasingly cheaper dye whose quality could be standardized. Natural-indigo prices fell sharply, and acreage contracted across India. By the eve of the First World War Bihar remained the principal surviving European-managed natural-indigo region, but on a much reduced scale. The crisis changed rural bargaining because planters tried to escape or monetize old indigo obligations as the crop itself lost profitability.

56.28 Contraction, substitution and regional adaptation

Decline took different forms. Some factories closed; some reduced acreage; some shifted toward direct cultivation, sugarcane or other crops; and some sought payments or rent adjustments in exchange for releasing tenants from indigo obligations. Darbhanga's recorded contraction after 1900 illustrates the process quantitatively, while Champaran shows how substitution could generate new agrarian grievances. Commercial agriculture therefore did not move neatly from "indigo" to "no indigo." Land, leases, factory property and contractual legacies survived the crop's market decline.

56.29 Champaran 1917–1918: from crop compulsion to statutory abolition

Champaran in 1917 brought these accumulated tensions into an official inquiry. Gandhi and local advocates collected tenant statements; the government appointed the Champaran Agrarian Committee, which recommended abolition of tinkathia. The Champaran Agrarian Act of 1918 made conditions requiring a tenant to set aside land for a particular crop void and regulated related disputes. This was not simply a moral verdict on indigo as a plant. It was a statutory intervention into the coercive use of tenancy contracts to compel commercial cropping.

Figure 223 — Chronology firewall for colonial indigo

56.30 Conclusion: commercial agriculture redistributed risk and power

Indigo reveals how colonial commercial agriculture redistributed risk. Planters and financiers sought control over a crop whose price was set in distant markets; cultivators supplied land, labour and ecological risk; factories converted plant into exportable dye; and the colonial legal order gave contracts and landed rights new enforceability. Regional arrangements differed across Tirhut, Darbhanga, Champaran, Bhagalpur and Monghyr, while synthetic dye eventually transformed the entire economic logic. Chapter 57 follows another commodity network in which the colonial state itself played an even more direct role: opium.

Table 56.1 — Cultivation systems and distribution of agrarian risk

System / institution	Who controlled land or crop?	Main distribution of risk / power
Nij / zerat cultivation	Factory directly controlled cultivated land and operations	greater planter control; factory bore more cultivation and labour costs
Assamiwar / ryoti cultivation	Tenant grew indigo under factory agreement	cultivator supplied land and family labour; planter influence strengthened by advances and tenure
Khuski cultivation	Independent cultivator contracted to supply crop	more bargaining distance from factory tenurial power; planters often had to offer better terms
Tinkathia in Champaran	Specified fraction of tenant holding reserved for indigo	crop compulsion embedded in tenancy agreement; not a universal Bihar system
Factory processing	Planter controlled vats, manufacture and grading	quality and industrial risk concentrated at factory stage
Synthetic indigo after 1897	World dye market shifted toward chemical manufacture	natural indigo prices and acreage fell; planter–tenant bargains were renegotiated

Chapter 57 — Opium and Other Commodity Networks

Opium turned Bihar into one of the most tightly regulated commodity landscapes of the British Empire. Yet the poppy was never the whole economy. Cultivators in Mithila, Vajji and Anga also produced grain, oilseeds, tobacco, sugarcane and indigo; specialist workers made and refined saltpetre; Bhagalpur sustained silk and tasar manufacture; lac and other forest-linked products moved through eastern markets. The historical problem is therefore not to isolate opium as an exotic drug crop, but to understand how a state monopoly operated inside a much broader field of private, licensed, illicit and subsistence exchange. This chapter follows the opium chain from advance to field, collection, Patna processing, Calcutta auction and Asian export, while comparing it with other commodity networks whose labour regimes, transport needs and degrees of state control were different. It also maintains a strict source hierarchy: cultivation records do not equal export statistics, factory output does not measure total local production, and late gazetteers must not be projected backward without period evidence.

57.1 Opium as a commodity system rather than a single crop

Opium joined agriculture to manufacturing, finance, transport and overseas commerce. A cultivator grew poppy, but the commodity recognized by the colonial state was the processed drug delivered, tested, mixed, packed and eventually sold through official channels. The difference matters because each stage redistributed control. The crop demanded irrigated and carefully prepared winter land; the agency system supplied advances and fixed delivery obligations; factory officers standardized quality; river transport moved chests eastward; and Calcutta auctions converted a Bihar-grown product into imperial revenue. The commodity chain therefore connected village households in the Gangetic plain to merchants and consumers far beyond India. It also created opportunities for leakage, bargaining and evasion at every link.

57.2 Patna had an opium economy before Company monopoly

Patna was already a major opium market before the East India Company became the dominant political power in Bengal and Bihar. Eighteenth-century evidence describes merchant syndicates and competing European companies purchasing the drug in and around Patna. The Company did not invent opium cultivation; it progressively subordinated an older commercial system. This distinction is essential for regional history. Precolonial merchants, money advances and long-distance trade created an infrastructure that the Company inherited and transformed. After political conquest, the Company increasingly used fiscal authority to control purchase and export. The resulting monopoly was therefore a reorganization of an existing commodity economy rather than the sudden appearance of a new crop.

57.3 From political conquest to commercial monopoly

Company victories at Plassey and Buxar and the acquisition of the Diwani changed the balance of power behind commodity contracts. By the mid-1760s the Company could combine commercial privilege with territorial revenue authority. Patna became especially important because it sat inside the principal Bihar production zone and on the Ganga route to Calcutta. The Company's opium profits were increasingly tied to its Patna establishment, while Dutch, French and other competitors lost room to operate. This was not yet the mature nineteenth-century agency system, but it created the political conditions in which a territorial government could attempt to regulate cultivation, purchase, processing and export as parts of a single monopoly.

57.4 The 1773 contract regime concentrated control

In 1773 Warren Hastings reorganized the trade by placing the opium monopoly under contract. Contractors received privileged access to procurement while cultivators and local dealers faced a shrinking legal market outside the official channel. The system relied on Indian commercial intermediaries and therefore did not eliminate indigenous capital. It changed the institutional location from which that capital could operate. Complaints of irregularity, coercion and declining quality accompanied the contract years. The state's objective was fiscal as much as commercial: it wanted a predictable stream of monopoly profit without bearing every operational cost directly.

57.5 From public contracts to the agency system, 1785–1799

In 1785 the Company experimented with auctioning the opium contract to the highest bidder. Revenue and quality problems persisted. By 1797 the contract system was abandoned, and in 1799 the Company formalized an agency system under covenanted servants. Patna and Benares became the two great centres of “Bengal” opium administration. Under the new arrangement the state moved closer to cultivators through advances, measured acreage, authorized cultivation and compulsory delivery of contracted produce at fixed rates. This did not produce complete control, but it marked the institutional form that defined nineteenth-century Bihar opium.

Figure 224 analytical field: the Bihar opium commodity chain

Analytical point: cultivation, manufacture, transport and overseas sale were institutionally distinct stages.

Figure 224 — The Bihar opium commodity chain

57.6 Annual advances tied cultivation to a state purchasing system

Under the mature Bihar agency system cultivators entered annual engagements to grow poppy on specified land. Government advances helped finance seed, irrigation and household needs before harvest, but the advance also tied the crop to official delivery. The arrangement should not be described simply as free purchase in an open market. The state was simultaneously regulator and buyer. Official descriptions stressed that cultivators could choose whether to engage, whereas critical testimony and later scholarship emphasize the unequal bargaining power created by debt, local officials and the absence of a legal competing buyer. Both dimensions belong in the analysis: formal voluntarism existed inside a monopolized market.

57.7 Poppy was agronomically demanding

Poppy competed for some of the best winter land. It required fine tillage, careful moisture management and repeated labour. Once the capsule matured, cultivators made shallow incisions and collected the latex over successive rounds. Yield therefore depended on household labour, irrigation, weather and skill as much as acreage. The crop's labour intensity helps explain why advances alone could not guarantee production. A household had to weigh the expected payment against food crops, tobacco, oilseeds and other rabi alternatives. In flood-prone north Bihar, the suitability of a tract also varied sharply with drainage and soil texture.

57.8 Measurement, testing and deductions made the contract concrete

The state monopoly became real through mundane practices: measuring contracted land, recording cultivators, weighing raw opium, testing consistency and purity, and calculating payments or deductions. These procedures turned a biological crop into an auditable fiscal commodity. They also created points of dispute. Cultivators could challenge measurement or quality deductions; officials worried about adulteration and diversion; local intermediaries mediated information between village and agency. The archival record is therefore rich in administrative detail but must be read critically. A regulation proves what officials wanted to happen, not necessarily what happened in every village.

57.9 Village intermediaries remained indispensable

Even a highly centralized monopoly depended on local knowledge. Headmen, money handlers, measurers, clerks, peons and other intermediaries helped identify cultivators, distribute advances, record acreage and assemble produce. Such actors could facilitate the system, extract side payments, shield cultivators or intensify pressure. The opium state was therefore not a direct line from Calcutta to the peasant. It was a layered local administration whose effectiveness varied by district and season. This helps explain why the same formal regulations could generate different practical outcomes in Tirhut, Shahabad, Saran or the eastern edge of the Bihar agency.

57.10 The monopoly chronology must not be flattened

The terms "Company opium" or "Patna opium" can conceal major institutional change. Merchant competition before territorial conquest, the 1770s contract regime, the 1785 auction experiment, the agency system after 1797–99, and the late nineteenth-century bureaucracy were not the same structure. Later evidence—especially the Royal Commission on Opium—describes a mature administrative system with decades of accumulated rules. It is valuable for understanding how the monopoly worked in the 1890s, but it cannot simply be read backward into 1773. A chronology firewall is therefore necessary throughout this chapter.

Figure 225 analytical field: chronology of Company control over Bihar opium

Chronology firewall: later nineteenth-century agency practice should not be backdated to the 1770s contract regime.

Figure 225 — Chronology of Company control over Bihar opium

57.11 Muzaffarpur and southern Tirhut formed an important poppy tract

Late nineteenth-century district evidence places opium among Muzaffarpur's major commercial crops and manufactures. The high southern tract, including the Hajipur side of the district and areas south of the Burhi Gandak, was especially associated with opium, indigo and tobacco. This spatial pattern is significant because it shows that cash crops clustered according to soil and drainage rather than administrative boundaries alone. It also places the Vajji-Hajipur zone inside the commercial agriculture of the middle Ganga plain. The evidence is strongest for the later nineteenth century; earlier acreage should not be inferred from later prominence without supporting records.

57.12 Opium shared land with indigo and tobacco rather than replacing them

Muzaffarpur is a useful reminder that colonial cash cropping was plural. District accounts list indigo, saltpetre, opium and tobacco together among important manufactures or crops. These commodities imposed different calendars and labour demands. Indigo was tied to factory processing and planter contracts; opium to a state purchasing monopoly; tobacco to a more private market; saltpetre to specialist extraction and licensed refining. A cultivator or village economy could therefore interact with several commercial systems at once. The history of commercialization is better understood as a portfolio of overlapping obligations and opportunities than as a sequence in which one crop completely displaced another.

57.13 Darbhanga shows the unevenness of poppy cultivation

Poppy did not occupy every part of Mithila at the same intensity. Evidence submitted to the Royal Commission on Opium in the 1890s records very uneven cultivation and even the absence of poppy on some large government-managed Darbhanga estates. Such testimony does not prove that the district as a whole had no opium economy; it does show that official monopoly territory and actual crop geography were different things. Flood risk, soils, irrigation, local crop preferences and estate policy all shaped adoption. Darbhanga should therefore be treated as an internally differentiated agrarian region rather than automatically grouped with the more intensively documented Muzaffarpur-Hajipur tracts.

57.14 The eastern edge of the opium belt reached toward Bhagalpur

Imperial gazetteer descriptions of the nineteenth-century opium system placed the eastern limit of successful poppy cultivation around Bhagalpur. That statement is useful as a broad geographical marker, not as proof that Bhagalpur resembled the core Bihar agency districts in acreage or dependence. Anga's commercial profile was more diversified. Bhagalpur district evidence gives greater prominence to indigo, silk and tasar, grain, oilseeds, tobacco, saltpetre and river trade. The region therefore connected to the opium world without being reducible to it.

57.15 Patna and Gulzarbagh converted raw opium into a standardized export product

The Patna factory at Gulzarbagh was one of the most visible institutional centres of the monopoly. Nineteenth-century drawings and descriptions show examining, mixing, balling, stacking and storage as distinct operations. Raw opium arrived in labelled containers, was checked for consistency and purity, mixed into standardized mass, formed into balls or cakes, dried and packed for transport. The factory's importance lay precisely in standardization: village produce varied, whereas auction buyers expected a recognizable "Patna" or Bengal opium product. Industrial discipline therefore linked the agrarian monopoly to the export market.

57.16 Factory labour was part of the commodity history

The factory was not an abstract state machine. It depended on large numbers of workers who examined, mixed, handled, shaped, dried, packed and moved the drug. Sherwill's mid-nineteenth-century images of the Patna factory are valuable because they make visible the human labour hidden inside revenue statistics. They also remind us that the opium economy created urban and peri-urban employment distinct from poppy cultivation. Porters, clerks, inspectors, boat crews and warehouse workers formed a labour chain between field and auction. Their wages and work discipline belong to the social history of the commodity.

57.17 The Ganga was an industrial transport corridor

Patna's location on the Ganga allowed processed opium to move east toward Calcutta. Transport required boats, crews, contracts, secure storage and timing. Research on boatmen in early colonial eastern India shows that monopoly commodities such as opium and saltpetre drew the state deeply into disputes over transport contracts. Delays, diversion of boats and labour conflict could disrupt a trade that official accounts often represent as smooth. River transport was therefore not merely a final logistical step. It was a field of bargaining in which boatmen, contractors, merchants and state officers negotiated the movement of high-value cargo.

57.18 Calcutta auctions separated production from overseas marketing

Once opium reached Calcutta, the Company sold chests through auction rather than itself carrying every shipment to China. This separated the territorial monopoly in cultivation and manufacture from the merchant networks that handled overseas trade. Auction revenue was central to the fiscal importance of the system, but auction figures cannot be used as a direct measure of conditions in a particular Bihar district. They record standardized chests entering the export market after multiple stages of collection and processing. The distinction between cultivation statistics and sale statistics is one of the most important methodological controls in opium history.

57.19 China made Bihar opium part of an imperial financial circuit

Bihar-grown opium became crucial to the Company's Asian balance of trade because sales to merchants involved in the China trade generated large revenues and helped finance the purchase of Chinese goods. The commodity thus linked cultivators who may never have travelled beyond their district to Canton, coastal shipping and imperial finance. Yet the profits realized at auction or overseas were not the cultivator's price. The chain was designed so that the state captured the difference between controlled procurement and competitive export sale. This gap between producer payment and monopoly realization was fundamental to the political economy of the system.

57.20 Malwa opium exposed the limits of monopoly

The Company's Bengal or Patna opium faced competition from Malwa opium grown in western and central India. Merchants moved Malwa opium through routes that did not depend on the Patna-Benares agency structure, and much of it reached the China trade despite Company attempts to regulate or tax it. The competition demonstrates that monopoly was a territorial project, not a complete control of the subcontinent's drug economy. Smuggling, legal ambiguity and merchant adaptation forced the Company to modify policy. For Bihar history, Malwa matters because external competition affected the price, scale and strategic value of Patna opium even when the rival drug was grown far away.

Figure 226 analytical field: regional commodity mosaic

The regions participated in overlapping markets, but no single commodity defined the whole Mithila-Vajji-Anga economy.

Figure 226 — Regional commodity mosaic across Mithila, Vajji and Anga

57.21 Illicit cultivation and diversion were built into monopoly politics

No monopoly of this scale could eliminate unauthorized cultivation or diversion. Cultivators could conceal acreage, adulterate deliveries, sell outside official channels or cooperate with private traders. Officials interpreted such practices as leakage and criminality; historians have also asked whether they represented bargaining or resistance against monopoly prices. The evidence does not support a single answer. Some diversion was commercial opportunism, some reflected local survival strategies, and some was organized merchant competition. The key point is that the existence of illicit trade reveals the gap between regulatory design and rural practice.

57.22 Opium revenue generated a moral economy as well as a fiscal one

By the late nineteenth century the opium system had become the subject of intense moral and political controversy. Missionaries, anti-opium activists, officials, merchants and Indian witnesses debated medical use, consumption, coercion and the legitimacy of a government profiting from the drug. The Royal Commission on Opium of 1895 assembled a massive record but was itself part of imperial politics. Its evidence must therefore be used both for the facts witnesses supplied and for the categories through which the state framed the controversy. Revenue, morality and agrarian practice were inseparable by this stage.

57.23 Saltpetre was a companion monopoly commodity with a different labour base

Saltpetre connected Bihar to imperial warfare and commerce long before the nineteenth century. Under Company rule it was often administered alongside opium because both were high-value products requiring procurement, quality control and transport to Calcutta. Yet its production ecology was different. Specialist workers collected nitrate-rich earth and processed crude saltpetre; refiners then purified it. The commodity therefore depended less on dedicating prime fields to a state crop and more on skilled extraction and refining. Treating opium and saltpetre together reveals how the Company applied monopoly principles to very different forms of rural production.

57.24 Muzaffarpur saltpetre linked specialist producers to licensed refiners

Late nineteenth-century Muzaffarpur accounts describe saltpetre refining as an important manufacture and refer to large numbers of licences. They also distinguish the refiners who purchased crude material from Nuniya or related specialist producer communities. This layered organization matters socially. The value added at refining did not necessarily return to those who gathered and processed nitrate earth at the first stage. The commodity network therefore reproduced occupational hierarchy as well as commercial profit. It also overlapped geographically with opium, indigo and tobacco, giving southern Tirhut one of the most diversified cash-commodity landscapes in the study region.

57.25 Bhagalpur's commodity economy was exceptionally diversified

Bhagalpur's nineteenth-century rail and river statistics show a commercial field in which grain, pulses, oilseeds, indigo, saltpetre, tobacco, silk goods, lac and other products moved simultaneously. The district's economy cannot be reconstructed from one celebrated commodity. Its Ganga location connected agricultural surplus and artisanal production to Patna, Calcutta and eastern river ports, while northward trade linked it indirectly to Nepal. This diversified profile is one reason to resist making opium the master narrative of colonial Anga. Opium belonged to the wider Gangetic system, but local prosperity and vulnerability depended on a changing basket of goods.

57.26 Silk and tasar linked Anga's craft labour to long-distance trade

Bhagalpur's silk and tasar traditions created a commodity chain different again from opium. Sericulture and the collection of cocoons fed reeling, spinning and weaving, while merchants connected cloth and yarn to wider markets. Colonial accounts sometimes described the industry as declining or changing under competition, but they also show its persistence as a recognizable regional manufacture. Silk depended on specialized artisanal knowledge and household labour rather than a state crop monopoly. Its inclusion in this chapter allows a comparison between coercive or highly regulated commodity systems and industries whose control lay more heavily with merchants, weavers and local producers.

57.27 Tobacco, sugar and oilseeds broadened commercial agriculture

Tobacco was prominent in parts of Muzaffarpur and other Bihar districts and entered private market channels rather than the opium monopoly. Sugarcane and jaggery connected village processing with town and river markets. Oilseeds moved in large bulk through Bhagalpur and other Gangetic centres. These commodities show that commercialization did not automatically mean export to Europe or China. Much exchange was regional or interregional within South Asia. The colonial economy therefore contained several scales at once: imperial monopoly, overseas export, Indian long-distance trade and local market circulation.

57.28 Lac, dyes and forest-linked products crossed the agrarian frontier

Lac and other forest-linked products complicate the division between “agricultural” and “non-agricultural” commodities. In the Bhagalpur-Santal interface, collection, cultivation, processing and trade connected forest users, cultivators, artisans and merchants. Lac could enter dye and resin markets that were themselves transformed by industrial substitutes. The commodity demonstrates that Anga’s economic region extended beyond ploughed fields into woodland and upland zones. A socio-economic history that follows only land-revenue records would miss these connections.

57.29 Transport, credit and bazaar institutions connected otherwise different commodities

Opium, saltpetre, grain, silk and tobacco had different production systems, but they shared infrastructure. Boats, carts, river ghats, railways, warehouses, bazars, money advances and merchant credit connected producers to larger markets. Patna, Hajipur, Muzaffarpur, Monghyr and Bhagalpur acted as nodes rather than isolated towns. The expansion of railways in the later nineteenth century changed the relative importance of river routes but did not erase older trading practices immediately. Commodity history is therefore also the history of transport labour, market institutions and credit relationships that allowed goods with very different regulatory regimes to circulate through the same regional spaces.

Figure 227 analytical field: evidence firewall for colonial commodity history

Figure 227 — Evidence firewall for colonial commodity history

57.30 Conclusion: monopoly and market coexisted in the same countryside

Opium made the colonial state unusually visible in Bihar’s countryside because it regulated cultivation, advanced money, purchased the crop, processed the drug and controlled legal sale. But the same villages and market towns were simultaneously embedded in less monopolized networks of saltpetre, tobacco, sugar,

grain, oilseeds, silk, lac and indigo. The resulting economy was neither a free market nor a single command system. It was a layered field in which state monopoly, landlord power, private trade, household subsistence, specialized craft labour and illicit exchange coexisted. Mithila, Vajji and Anga participated differently within that field: southern Tirhut and Hajipur were important cash-crop zones, Patna was the great processing and commercial node, and Bhagalpur-Anga maintained a more diversified riverine and artisanal economy. The next chapter turns from commodities themselves to the transport revolution that altered the cost and geography of moving them: roads, steam navigation and railways.

Table 57.1 — Commodity systems and their different forms of control

Commodity / network	Regional evidence	Institutional / chronology caution
Opium	Muzaffarpur-Hajipur poppy tracts; Patna agency/factory; eastern limit toward Bhagalpur	State monopoly, advances and fixed delivery; factory/auction data are not district acreage data.
Saltpetre	Muzaffarpur, Saran, Patna-Bihar trade; also Bhagalpur commerce	Specialist extraction and refining; distinct from dedicating fields to a monopoly crop.
Tobacco	Strong in parts of Muzaffarpur and other Gangetic districts	Private commercial crop; should not be folded into the opium agency system.
Silk / tasar	Bhagalpur-Anga artisanal and merchant networks	Craft/sericulture chain; later decline narratives do not erase earlier persistence.
Grain / oilseeds	Bhagalpur river and rail traffic; regional market surplus	Bulk trade statistics are dated snapshots, not permanent crop shares.
Sugar / jaggery	North Bihar and Gangetic market circuits	Village and regional processing preceded later factory sugar industry.
Lac / dyes	Bhagalpur-Santal interface and eastern market networks	Forest-linked production crosses the agrarian/non-agrarian boundary.

Chapter 58 — Famines, Scarcity and Food Security

Scarcity has repeatedly exposed the relationship between ecology, markets, household resources and public authority in Mithila, Vajji and Anga. A failed monsoon or damaged rice crop could begin a crisis, but famine emerged only when households lost effective access to food: grain prices rose faster than wages, cattle and tools were sold, seed was eaten, credit contracted, employment failed, or transport could not move food from surplus to deficit areas. The same region therefore experienced radically different outcomes in 1770, 1873–74 and 1896–97. In 1769–70 severe drought interacted with Company revenue extraction, grain procurement, weak relief and epidemic disease to produce catastrophic mortality in Bihar. In 1873–74, by contrast, the colonial government imported enormous quantities of rice, created depots, organized transport and inspected villages on a scale unprecedented in the province; mortality was correspondingly much lower, though the operation was criticized as excessively expensive. The famine of 1896–97 showed a third pattern: formal famine codes and improved communications existed, yet distress was sharply uneven, with Darbhanga requiring very large relief operations while parts of north Monghyr escaped crop failure but still suffered high prices among the landless poor. This chapter therefore treats famine not as an event label but as a social process. It reconstructs scarcity through harvests, prices, wages, entitlements, migration, relief and mortality, and it keeps contemporary evidence separate from later administrative memory. The history of food security is the history of how these layers were connected—and of how public policy sometimes broke, and sometimes failed to break, the chain.

58.1 Famine is a social process, not simply a failed harvest

Rainfall failure is an environmental shock; famine is a social outcome. A district can harvest less grain without experiencing mass starvation if households possess stocks, wages, livestock, credit, kin support or access to imported food. Conversely, even a moderate regional shortfall can become dangerous when prices rise rapidly and people who depend on daily earnings lose purchasing power. This distinction is essential in the flood-prone and river-connected landscapes of Mithila, Vajji and Anga. Wet rice agriculture was vulnerable to both drought and destructive inundation, but rivers also moved grain, supported fisheries and connected deficit zones to markets. The chapter therefore uses “scarcity” for serious stress in food availability or access, and reserves “famine” for crises involving widespread destitution, exceptional relief or excess mortality. That vocabulary prevents every poor harvest from being retroactively labelled a famine and makes comparison possible across very different administrative regimes.

58.2 Food security had four linked dimensions: harvest, market, household and state

The historical evidence becomes clearer when divided into four layers. The first is production: rainfall, floods, crop area and harvest outturn. The second is exchange: local prices, imports, exports, grain dealers, transport and market integration. The third is household entitlement: wages, rents, debt, livestock, seed, employment and the capacity to claim food through market or social relations. The fourth is public action: revenue suspension, grain procurement, depots, charitable relief, public works, medical care and later famine-code administration. A collapse at one layer did not automatically produce collapse at the next. Grain could exist in a province while the poor could not buy it; relief could be announced but arrive too late; transport could reduce prices in a market town while remote villages remained exposed. A source-critical famine history therefore asks at which layer the evidence is speaking.

58.3 The regional ecology produced both abundance and recurrent risk

Mithila's alluvial plains, the Gandak and Kosi systems, the Ganga corridor through Vajji and the riverine tracts of Anga generated fertile agriculture but also recurrent uncertainty. Winter rice depended on the timing and distribution of rain; low-lying lands could be flooded while neighbouring high ground suffered moisture stress. In north Bihar, rivers changed channels and damaged communications precisely when grain movement became urgent. South of the Ganga and in the eastern districts, local soil and crop mixtures differed, so the same monsoon did not generate identical outcomes. Colonial reports often described "Bihar" as one relief field, yet district experience could diverge sharply. This environmental diversity is why a regional chapter must resist both climatic determinism and administrative averages. Food security depended on the interaction between local ecology and the ability to move food, labour and credit across it.

58.4 Grain prices were often a more immediate danger to the poor than aggregate shortage

For landless labourers, artisans, servants and marginal cultivators, the decisive signal of scarcity was not a crop percentage but the price of the next meal. A household that purchased most of its food was exposed when rice or other staples rose faster than wages. Cultivators could also become buyers after exhausting stocks, losing a crop, paying rent or selling grain under debt pressure. Price therefore translated harvest shocks into unequal social consequences. Colonial officials increasingly monitored prices because sharp increases could reveal distress before mortality became visible. Yet price statistics themselves require caution: quotations from a town market did not automatically describe remote villages, and a fall in price after imported grain reached a depot did not prove that every household possessed cash to buy it. Market integration mattered, but entitlement determined who benefited.

58.5 The 1768–69 drought created a deteriorating subsistence base before the catastrophe of 1770

Contemporary Company records describe unusually severe drought in Bengal and Bihar during 1769, after earlier crop weakness had already raised concern. Bihar was repeatedly singled out as especially affected. The sequence matters. Scarcity did not begin suddenly in January 1770; households entered the worst months after harvest failures, rising prices and reduced reserves had already weakened them. Grain procurement for armies and official establishments added demand to stressed markets. Company servants and private traders were accused of monopoly and speculative practices, although the scale of such activity varied and should not be treated as the sole cause. The famine emerged from the conjunction of drought, market stress, revenue pressure and limited administrative capacity. Climate was necessary to explain the shock, but not sufficient to explain the mortality that followed.

From harvest shock to famine: a social process

Figure 228 — From harvest shock to famine: a social process

58.6 Patna provides unusually vivid contemporary evidence for the famine of 1770

Patna's surviving correspondence makes the crisis visible at street level. In January 1770, the Bihar supervisor reported that roughly fifty to sixty people had been dying daily of hunger in the city for several days. By late April, reports described still more extreme mortality and rapid depopulation in the interior. Officials also confronted thousands of beggars, abandoned children and the problem of disposing of bodies. These observations should not be mechanically extrapolated to calculate a provincial death toll, but they demonstrate that famine was not an abstract shortage in the revenue books. The urban centre drew destitute migrants from surrounding countryside, making mortality visible where grain, officials and charitable resources were concentrated. Patna thus shows both the magnitude of distress and the limits of using city observations to represent every rural locality.

58.7 Tirhut, Darbhanga and the eastern districts were not peripheral to the 1770 disaster

Later district histories and contemporary references indicate severe effects beyond Patna, including in Tirhut/Darbhanga, Bhagalpur and Purnea. The famine left a long administrative memory of abandoned cultivation, weakened revenue-paying households and delayed reclamation in parts of north Bihar. Yet retrospective claims—such as fractions of population lost—must be treated as estimates rather than census facts. What is secure is the structural pattern: mortality, migration and the sale or consumption of productive assets reduced the capacity to cultivate the next season. The consequences therefore continued after rains returned. Fields without labour, households without cattle, and villages without seed could not recover immediately. The 1770 famine was simultaneously a demographic, agrarian and fiscal crisis.

58.8 Revenue pressure deepened vulnerability even when remissions were discussed

The Company's recent acquisition of the Diwani meant that famine unfolded inside an administration strongly oriented toward revenue realization. Officials debated reductions, collection in kind, cultivation incentives and temporary concessions for coarse grains. Some reports warned that pressing revenue in a

devastated countryside would destroy future collections as well as cultivators. Nevertheless, later reconstructions show that revenue demand remained remarkably persistent. The important analytical point is not that every official pursued identical policy, but that relief and revenue were institutionally entangled. A remission could preserve seed and livestock; continued collections could force sales at precisely the moment when prices were most adverse. Fiscal policy therefore formed part of food-security history because it shaped household command over grain, not merely state income.

58.9 Grain procurement and market intervention were limited and often contradictory in 1770

The Company ordered grain stocks for troops and attempted to discourage monopolization, while some officials distributed rice or encouraged cultivation of drought-tolerant grains. Yet the scale and coordination of relief remained small relative to the crisis. Military procurement could also compete with civilian demand. Transport was slow, information fragmentary and public responsibility for subsistence had not yet been organized into the later famine-relief machinery. This institutional weakness distinguishes 1770 from 1873–74. The state possessed fiscal and coercive reach, but not a comparable apparatus for village inspection, mass grain import, depot management and standardized relief works. That mismatch—strong revenue extraction alongside weak subsistence protection—is one of the central features of the early Company famine regime.

58.10 Mortality in 1770 was produced by hunger, disease and social dislocation together

Famine deaths are rarely separable into neat categories of “starvation” and “disease.” Undernutrition weakened resistance to infection; migration crowded towns and roads; contaminated water and the accumulation of corpses increased sanitary risk; smallpox and other disease could circulate through already weakened populations. Contemporary reports from Patna explicitly feared pestilence in addition to hunger. The most defensible interpretation is therefore one of combined crisis mortality. This also cautions against reading later famine returns as direct measures of caloric deprivation. Mortality followed a chain in which food access, disease environment, mobility and relief all interacted. The distinction is important for comparative history: 1873–74 could avoid large-scale mortality not simply because more grain existed, but because transport, relief and administrative surveillance prevented destitution from progressing as far down this chain.

Comparison is analytical, not a single mortality scale: sources, administration and transport capacity changed radically.

Figure 229 — Three scarcity regimes in Bihar, 1769–1897

58.11 The famine reshaped land, labour and settlement after the rains returned

Recovery required more than a good harvest. Households had lost cattle, implements, seed, jewellery and credit; labour had migrated or died; cultivated land had fallen out of use. Later descriptions of north Bihar linked stretches of uncultivated land to the long aftermath of the 1770 famine as well as to oppressive revenue practices. Such retrospective statements cannot map every abandoned field, but they capture a real mechanism. Famine destroyed productive capital at household scale. Reclamation therefore depended on renewed labour supply, cattle ownership, credit and security of tenure. The agrarian history of scarcity must include this slow recovery because the social cost of famine persisted long after market prices normalized.

58.12 Golghar symbolizes the administrative memory of scarcity more than an effective famine system

The great granary at Bankipur, later known as Golghar, was completed in 1786 in the context of repeated official concern about provisioning and famine. Its architectural presence has made it a powerful symbol of the 1770 catastrophe. Yet the structure did not become the foundation of a comprehensive grain-security regime, and later accounts note practical limitations in its use. Its historical significance is therefore institutional and mnemonic. The state had learned that military and urban provisioning required stored grain, but storage alone could not solve the problems of harvest intelligence, rural purchasing power, transport, village relief and disease. Golghar reminds us that food security is a system rather than a building.

58.13 Between 1770 and 1873 the colonial state accumulated information and transport capacity

The century after 1770 transformed the administrative environment in which scarcity was managed. District officials produced increasingly regular reports on crops and prices; roads and river transport improved; railways began to alter the speed and scale at which grain could move; statistical gazetteers and revenue surveys described local production. Charitable relief and public works also became more institutionalized. None of this eliminated famine. Market integration could expose districts to external demand, and official information could be inaccurate or late. But by 1873 the government possessed logistical tools that had scarcely existed in 1770. The contrast between the two crises therefore reveals institutional change as clearly as climatic variation.

58.14 The 1873–74 Bihar scarcity began with failure of the rice crop in north Bihar

The crisis of 1873–74 followed deficient rainfall and serious failure of the main rice crop across parts of Bihar and adjoining Bengal. Tirhut was among the most threatened districts. Contemporary officials feared that millions might require assistance for months. The danger was heightened by the geography of north Bihar: the Ganga separated the principal import routes from districts such as Tirhut, while local roads and river crossings could slow distribution. Unlike 1770, however, the impending crisis was recognized early enough for large-scale preparation. The problem became one of moving grain into the threatened zone before household reserves and purchasing power collapsed.

58.15 Early warning transformed the 1873–74 response

By the autumn of 1873 government correspondence already treated Bihar as a major relief problem. Crop reports, market prices, district estimates and tours by senior officials were used to calculate likely requirements. These estimates were imperfect and often revised, but the administrative objective had

changed: officials attempted to act before mass mortality. Sir Richard Temple was sent through the affected districts to assess transport and relief needs, while local committees and district officers gathered information at finer scales. The innovation was not merely statistical. Early warning justified procurement, transport works and depot construction before famine conditions reached their worst. This preventive orientation marks one of the clearest differences from 1770.

58.16 Massive grain import made 1873–74 a logistics experiment

The government purchased and imported hundreds of thousands of tons of rice, much of it from Burma, to create a reserve against anticipated scarcity. The exact totals vary by accounting category, but the operation was extraordinary by nineteenth-century standards. Grain had to be shipped to Bengal, moved upriver or by rail, crossed the Ganga and then distributed through depots toward threatened districts. Importing food did not automatically feed the poor; it first had to alter local availability and prices or be issued through relief. The 1873–74 operation therefore demonstrated that famine policy depended on transport engineering, storage, contracting and district administration as much as on charitable intent.

58.17 The temporary line toward Darbhanga turned relief into infrastructure

Tirhut's transport difficulty produced one of the most striking legacies of the famine response. A temporary railway from the Ganga toward Darbhanga was built with exceptional speed to carry relief supplies into north Bihar. Contemporary railway reporting described a line of roughly fifty-three miles opened after only about fifty-three days of work and capable of moving large quantities of grain. The emergency line later formed part of the Tirhut railway system. This episode illustrates how famine relief could generate durable infrastructure. Yet it should not be romanticized: railways did not by themselves guarantee household entitlement to food. Their immediate importance was to reduce the cost and delay of moving grain into a threatened district.

58.18 Depots and village inspection tried to connect imported grain to local need

The government established grain depots and organized systematic inspection of villages to identify distress. The aim was to avoid waiting until starving migrants appeared at district headquarters. Village-level inspection could distinguish people able to work from those requiring gratuitous support and could reveal places where market prices or local stocks were most dangerous. Such classification later became central to famine-code administration. It also created new problems: officials had to decide who qualified, how frequently villages should be visited, and whether relief tests excluded the proud, immobile or socially marginalized. Administrative visibility expanded, but it did not become neutral.

58.19 Relief works converted public spending into both food access and infrastructure

Able-bodied recipients were commonly directed toward public works—roads, embankments, transport lines and earthwork—while wages or rations were intended to preserve purchasing power. The principle linked relief to labour, partly from a fear that unconditional assistance would create dependency. In practice, the labour test had to be softened when people were too weak, socially unused to manual work, or unable to reach worksites. Food could also be issued instead of cash when prices rose so high that wages no longer purchased an adequate ration. The 1873–74 experience thus exposed a persistent famine-policy dilemma: how to provide enough assistance to prevent destitution while satisfying official demands for economy, discipline and proof of need.

58.20 Gratuitous relief remained essential for those who could not work

Children, older people, the sick, nursing mothers and others unable to perform labour could not be protected by public works alone. Gratuitous relief, charitable kitchens and local assistance therefore formed a second pillar of the response. Darbhanga reports from later famines show how large such categories could become. The division between “workers” and “dependants” became a bureaucratic tool, but real households were more complex: the wage of one worker might support several non-workers, while illness could move a person rapidly from one category to another. Effective food security required relief rules flexible enough to reflect household dependency rather than treating every recipient as an isolated adult labourer.

1873–74 Bihar relief architecture

Key shift: famine relief became a logistics problem as well as a charitable or revenue question.

Figure 230 — Relief architecture in the Bihar scarcity of 1873–74

58.21 The low mortality of 1873–74 became both a policy success and a political controversy

Large-scale relief prevented the Bihar scarcity of 1873–74 from reproducing the mortality of 1770. Contemporary and later assessments generally regard the operation as unusually successful in saving lives. Yet success produced criticism because the government imported more grain than ultimately proved necessary and spent heavily on relief and transport. The surplus was interpreted by fiscal critics as evidence of extravagance rather than as insurance against uncertainty. That controversy mattered far beyond Bihar. It shaped the political climate in which later officials, including Temple himself, emphasized economy, task standards and stricter relief in other famines. The lesson drawn from Bihar was therefore contested: one reading celebrated prevention; another warned against the cost of acting too generously before exact need could be known.

58.22 Relief policy after 1874 increasingly sought rules, thresholds and codes

The repeated famines of the 1870s pushed the colonial state toward standardized famine administration. The Indian Famine Commission of 1880 recommended systematic monitoring, relief works, gratuitous relief for the incapable, and administrative preparation before crisis. Provincial famine codes later translated these principles into stages of scarcity and famine, price and crop indicators, wage or ration scales, and duties for district officers. Codes did not guarantee humane outcomes; rules could be interpreted restrictively, and the nutritional adequacy of relief wages became deeply contested. Still, the code system marked a transition from improvisation toward a formal claim that famine prevention was an administrative responsibility.

58.23 Famine codes changed what the state measured

Once scarcity management became codified, officials required information that could trigger action. Crop forecasts, rainfall reports, grain prices, wages, migration, cattle sales and employment conditions acquired new bureaucratic significance. Numbers were intended to make distress legible, but they could also conceal it. A district average might mask a devastated tract; reported wages might not account for irregular employment; market prices might not measure access among people without cash. The history of famine codes is therefore also a history of statistical power. Indicators made earlier intervention possible, yet they could narrow official perception to what was countable.

58.24 The famine of 1896–97 revealed sharp regional inequality within Bihar

The 1896–97 crisis demonstrates why district-level evidence matters. Darbhanga experienced major distress and very large relief operations after crop failure. Gazetteer accounts record hundreds of thousands on relief at the peak and substantial grain imports, while emphasizing relatively low mortality during much of the emergency. By contrast, census and gazetteer evidence for north Monghyr states that the crop was comparatively good and the district escaped formal famine, although landless poor people still suffered from high prices caused by scarcity elsewhere. The same regional market could therefore transmit price stress into a district without transmitting the original harvest failure. “Famine area” and “food-insecure household” were not identical categories.

58.25 Darbhanga in 1897 shows the mature colonial relief apparatus at scale

By 1897 the Darbhanga administration could mobilize relief works, gratuitous assistance and imported grain on a scale that would have been impossible in 1770. Gazetteer summaries report a peak relief population exceeding two hundred thousand and large grain imports. The exact totals are less important than the institutional transformation they represent. Relief was now budgeted, classified and reported in standardized units. Officials could also connect emergency works to longer-term infrastructure. Irrigation channels in parts of Madhubani were constructed during the famine and later helped protect winter rice in subsequent monsoon failure. Famine policy could therefore leave durable water-management as well as transport legacies.

58.26 Market integration could protect consumers and also transmit scarcity

Railways and steam transport reduced the isolation of local markets. Grain could move more quickly into a deficit district, limiting extreme price divergence and making large relief imports practical. But integrated markets also transmitted demand and price movements across regions. North Monghyr’s experience in 1896–97 is instructive: a relatively good crop did not fully insulate landless consumers from high prices generated by famine elsewhere. Market integration should therefore not be equated with automatic food security. It expanded the geographical scale on which grain could circulate, while household purchasing power still determined access.

58.27 Household coping strategies reveal the hidden cost of scarcity

Before appearing on a relief roll, households usually exhausted private strategies. They reduced meal size and variety, borrowed grain or money, postponed rent, sold livestock and jewellery, mortgaged land, sent members to seek work, gathered wild foods or withdrew children from school and productive apprenticeships. Some of these actions preserved life but damaged future livelihoods. Selling a plough animal or consuming seed grain converted a short harvest shock into a multi-year recovery problem. Because official

records often capture people only after they sought relief, these household costs are easy to underestimate. Food-security history must therefore reconstruct what people sacrificed before becoming administratively visible.

58.28 Famine burden was unequal by class, gender, age and occupation

Scarcity did not affect a village uniformly. Landless labourers and artisans dependent on daily purchases were usually exposed early to price inflation. Small cultivators could lose both crop and credit. Women often absorbed reductions in household consumption and could face increased care burdens when disease spread; widows and people outside strong kin networks were especially vulnerable to exclusion from private support. Children were threatened by both undernutrition and epidemic disease. Caste and occupational position influenced access to employers, landlords, charitable networks and village resources. Colonial relief categories recognized some of these differences only imperfectly. A social history of famine therefore cannot be reduced to aggregate mortality or district grain balances.

58.29 Disease, sanitation and public health were inseparable from food relief

As in 1770, mortality during later scarcity could arise through epidemics intensified by undernutrition, migration and poor sanitation. Relief camps and works concentrated populations; water sources could become contaminated; weakened people were more susceptible to infection. By the late nineteenth century famine administration increasingly incorporated medical inspection, camp sanitation and attention to water supply, although practice varied. This broadened the meaning of food security. Saving lives required more than supplying calories. It required preventing the secondary disease environment that turns hunger into mass mortality. The comparison across the three scarcity regimes therefore points toward a combined model of nutrition, public health and mobility.

Evidence firewall for famine and food-security history

Do not infer famine directly from drought, or mortality directly from grain shortage.

Regional comparison requires dated evidence at each layer; later gazetteers can preserve memory but cannot replace contemporary records.

Figure 231 — Evidence firewall for famine and food-security history

58.30 Conclusion: food security depended on institutions that could interrupt the chain from shock to destitution

The famine history of Mithila, Vajji and Anga is not a simple progression from bad government to good administration. The record is more uneven. In 1770 a severe climatic shock struck a countryside already exposed to revenue pressure and weak relief capacity, producing catastrophic mortality and long agrarian after-effects. In 1873–74 early warning, large imports, transport investment, depots and relief prevented comparable mortality, but the expense generated a fiscal backlash that influenced later policy. In 1896–97 a mature code-based apparatus coexisted with sharp regional and social inequalities: Darbhanga required massive intervention, while parts of Monghyr escaped crop failure yet still transmitted high prices to the

poor. The durable lesson is institutional rather than climatic. Famine becomes avoidable when information, transport, purchasing power, relief and public health act quickly enough to stop households from selling the assets on which their next harvest depends.

Table 58.1 — Major scarcity episodes and what they reveal about food security

Episode / region	What the evidence shows	Interpretive caution
1769–70: Bihar	Drought, crop failure, price escalation, severe Patna mortality, depopulation and weak relief.	Provincial death totals are estimates; city mortality cannot be extrapolated mechanically.
1873–74: Tirhut / north Bihar	Early warning, mass grain import, depots, village inspection, public works and temporary railway construction.	Large procurement does not equal grain consumed; surplus stocks were part of preventive insurance.
1896–97: Darbhanga	Large relief works and gratuitous relief, substantial grain imports, comparatively low mortality during much of the crisis.	Administrative relief units measure service delivered, not unique persons or caloric adequacy.
1896–97: north Monghyr	Relatively good crop; formal famine largely avoided, but landless poor faced high prices transmitted from elsewhere.	Absence of crop failure does not mean absence of household food insecurity.
Long-run lesson	Transport, market access, household entitlement, relief and public health jointly shaped outcomes.	Do not infer famine directly from drought, or mortality directly from grain shortage.

Chapter 59 — Colonial Surveys and the Invention of Social Categories

Colonial surveys created an extraordinarily dense archive for the social history of Mithila, Vajji and Anga, but the archive must be read as a history of classification as well as a description of society. From Buchanan-Hamilton's early district inquiries to the censuses, Risley's ethnography, Grierson's linguistic survey and the gazetteers, officials progressively standardized names, boundaries and comparative tables. The central method of this chapter is chronological: a colonial category is evidence first for the date and administrative purpose in which it appears. It cannot be projected backward without independent period evidence.

59.1 Colonial knowledge became an instrument of administration

Colonial rule generated an expanding demand to describe the people it taxed, policed, recruited, litigated with and governed. The resulting surveys were never neutral inventories. Their headings reflected administrative problems: landholding, occupation, religion, language, "tribe," "caste," custom and rank. Yet it is equally misleading to treat every category as a pure colonial fabrication. Officials worked with locally supplied names, inherited textual vocabularies, previous revenue records and the testimony of intermediaries. The historical problem is therefore to reconstruct a process of translation. Social identities existed before the census, but the survey and census increasingly required them to be written into standardized boxes, compared across districts and made legible to provincial government. The documentary archive is invaluable precisely because it records this encounter between lived social description and bureaucratic classification.

59.2 The Company survey preceded the decennial census by decades

Long before all-India decennial enumeration, the East India Company commissioned district surveys to learn the economic and social character of its territories. The sequence associated with Francis Buchanan-Hamilton in eastern India between 1807 and 1814 covered Purnea, Bhagalpur, Bihar and Patna, Shahabad and neighbouring districts. His questionnaires ranged far beyond revenue. They recorded cultivation, manufactures, markets, prices, diseases, religious establishments, learned specialists, languages and divisions among the population. The form was encyclopaedic because the Company still lacked a settled statistical apparatus. For Mithila, Vajji and Anga, these early reports are therefore a baseline for the early nineteenth century, not a transparent survival of medieval society. Their strength is descriptive breadth; their weakness is the mixture of direct observation, local testimony, estimation and authorial judgement.

59.3 Buchanan-Hamilton's method joined observation to local testimony

Buchanan-Hamilton travelled, questioned officials and residents, inspected institutions and compiled numerical returns, but he could not personally verify every statement in large districts. His accounts make visible the people who supplied information even when they are not always named: revenue servants, landholders, merchants, religious specialists, cultivators, artisans, physicians and interpreters. A social category in his report should therefore be read as a negotiated entry produced through a chain of communication. The same label might carry different meanings in different localities, while a local term might be translated into an English administrative vocabulary that made it appear more uniform than it was. This is why the reports are best used comparatively, alongside settlement papers, genealogical records, vernacular materials and later gazetteers, rather than mined for isolated timeless statements about communities.

59.4 Early surveys mixed social, occupational and religious classifications

The early district accounts did not yet possess the rigid appearance of later census tables. Descriptions could move between occupation, lineage, sect, locality, status, religion and customary practice without forcing each person into a single analytical axis. That fluidity is important evidence. It reminds us that later census columns were not merely recording a pre-existing universal taxonomy. A cultivator might also be described through a caste name, a tenancy relation, a sectarian affiliation and a regional label; a learned specialist could be located simultaneously in a scholastic institution and a kin network. Historians should preserve those overlaps. Reducing an early survey entry to one modern identity category can erase exactly the ambiguity that makes the source useful for tracing how social classifications changed during the nineteenth century.

59.5 Revenue knowledge and social knowledge were intertwined

Survey categories gained administrative weight because they were linked to fiscal and legal questions. Officials wanted to know who held land, who cultivated it, what services were customary, which groups migrated, which occupations supported particular markets and how local authority operated. Land and revenue classification therefore shaped social description even when the report's chapter title concerned "the people." In Permanent Settlement districts, the distinction among proprietors, tenure-holders, tenants and labourers could be as consequential as caste terminology. Conversely, officials sometimes interpreted agrarian relations through assumptions about community or hereditary occupation. The archive must be read in both directions. Social labels could influence administrative reasoning, while administrative forms could make some dimensions of social life more visible than others.

Colonial classification was a chain of translation, not a direct photograph of society

Names could be selected, merged, split, standardized, ranked or reinterpreted at each stage.

Figure 232 — From local description to administrative category: the colonial classification chain

59.6 Hunter's Statistical Account made the district a comparative statistical unit

By the 1870s the government possessed a denser archive of revenue returns, censuses, police reports, road and trade information and district correspondence. W. W. Hunter's Statistical Account of Bengal assembled this material into volumes organized by district. Tirhut and Champaran appeared in Volume XIII; Patna and neighbouring districts were treated in other volumes. These accounts combined geography, population, agriculture, landholding, trade, institutions and administrative statistics. Their importance lies less in any single number than in the new comparative form: districts could now be tabulated against one another. The method encouraged standard headings and recurring variables, making society increasingly visible as a set of measurable attributes. At the same time, local complexity was compressed to fit the provincial statistical template.

59.7 The 1872 enumeration was a major experiment rather than a fully standardized modern census

The census taken across the Bengal Presidency in 1872 marked a new scale of population enumeration. Its reports discussed the accuracy of returns and the problems of supervision, showing that the operation itself was understood as experimental. For Bihar districts, surviving census publications and divisional statements provide population counts and classifications that can be compared with Hunter's statistical compilations. But "1872" should not be treated as if it had the uniform procedures of a later national census. Dates, forms and administrative arrangements varied across British India, and enumerators depended heavily on district machinery. The value of the exercise is therefore double: it produced new quantitative evidence, and it reveals the practical difficulties involved when government attempted to translate millions of households into a centralized statistical language.

59.8 Enumeration was mediated by local clerks, household informants and officials

A census schedule did not fill itself. Enumerators had to ask questions, interpret answers, choose spellings, resolve synonyms and assign entries to printed headings. Household informants could answer strategically or according to local usage; clerks might regularize unfamiliar names; district officers could merge small categories or separate large ones when compiling tables. Social knowledge was thus co-produced, although the state controlled the final classificatory architecture and publication. Recognizing local participation does not remove the asymmetry of colonial power. It explains why the archive can contain both indigenous vocabularies and bureaucratic distortions at the same time. The historian's task is to reconstruct the chain from answer to schedule to table instead of assuming that the published category was the only identity available to the person enumerated.

59.9 The 1881 census regularized decennial enumeration

The 1881 census brought a more systematic and synchronized framework to British Indian population statistics. The Bengal report included major sections on caste, birthplace and language, occupations, instruction and illiteracy. Repeated census-taking created comparability across decades, but it also increased pressure for stable definitions. A category that changed name or boundaries created a statistical discontinuity, so officials increasingly documented classification rules. This administrative need could encourage the appearance of sharper social boundaries than everyday life displayed. The gain for historical research is substantial: recurring tables make it possible to study demographic structure, literacy, occupation and migration. The cost is that the repeated form can tempt readers to mistake the state's need for commensurability for evidence that every social category was fixed and universally agreed.

59.10 A printed table made fluid answers appear mutually exclusive

Tabulation is an intellectual act. When thousands of written answers are aggregated, variant spellings and local subdivisions must be assigned to headings, while ambiguous cases are resolved so that column totals add correctly. The printed page then hides much of that editorial labour. This is especially important for caste, tribe, language and occupation. A table can make a category look bounded because every row has a line and every number occupies one cell. Yet the original social world may have contained overlapping affiliations, status disputes and multilingual households. Statistical exactness at the final stage should therefore not be confused with ontological exactness. The numbers may precisely reproduce the rules of compilation while those rules themselves simplify social reality.

From district survey to standardized enumeration and classification

Figure 233 — Major stages in the nineteenth-century classificatory archive

59.11 Caste names in colonial records were situated claims, not medieval fossils

When a census or gazetteer records a caste name, the safest first conclusion is that the name was used or recognized in that administrative setting at that date. More ambitious historical claims require earlier evidence. Some designations had long histories; others changed scope, acquired new prestige, split into subgroups or were standardized only in the nineteenth century. The colonial archive is exceptionally rich for studying these transformations because officials repeatedly asked about rank, marriage, occupation and custom. It becomes misleading only when its categories are projected backward without chronological control. The present volume therefore treats a colonial caste label as evidence for colonial social history unless inscriptions, dated genealogies, manuscripts, Panji material or other earlier records independently establish an older chronology.

59.12 Occupation and caste were related but never interchangeable

Colonial officials often searched for correspondences between caste and hereditary occupation, partly because such correspondences promised an intelligible social system. District evidence repeatedly complicated that assumption. Cultivators could belong to many named communities; service groups could combine agriculture with specialized work; merchants and artisans moved between occupations; landholding altered status; migration created new labour combinations. Census occupational tables therefore answer different questions from caste tables. They are strongest when used to reconstruct the distribution of work at a particular time, not when used to infer an unchanging occupational essence for a community. For Mithila, Vajji and Anga, this distinction is especially important in a nineteenth century transformed by indigo, opium, railways, urban services, migration and expanding clerical employment.

59.13 Religious classification also required administrative boundaries

Religious enumeration appears simpler than caste classification only when later categories are taken for granted. Census officers had to decide how to count sects, reform movements, local devotional identities and people whose practice crossed neat textual boundaries. Gazetteers often described popular worship, pilgrimage and local cults in ethnographic detail, while census tables reduced religion to a smaller set of aggregate headings. Both source types are useful, but for different purposes. The table measures the administrative population assigned to a category; the descriptive chapter records a selective account of practice. Neither should be substituted for the other. Ritual participation, sectarian affiliation and census religion were related dimensions of social life, not necessarily identical ones.

59.14 Language classification converted multilingual practice into named languages

The same methodological problem appears in language statistics. Households could use one speech form at home, another in markets, a different literary language and yet another language in school or administration. Census forms nevertheless required a countable answer. Officials had to decide whether a local name denoted a separate language, a dialect or a synonym. The resulting tables are essential for studying the history of language naming, but they do not map speech mechanically. In Mithila, Vajji and Anga, later distinctions among Maithili, Angika, Bajjika, Hindi/Hindustani and other administrative language labels must be interpreted through the wording and classification rules of each source. Modern political or constitutional language categories cannot be read backward into every colonial table.

59.15 Hunter's accounts linked population categories to economy and administration

One advantage of the Statistical Account over isolated census tables is that it places population categories beside agriculture, markets, education, transport, land revenue and public institutions. This permits a genuinely socio-economic reading. A group's numerical presence can be examined alongside the district economy in which people lived, without assuming that the group itself explains the economic pattern. Hunter's compilations also preserve the administrative state of knowledge in the 1870s: what officials thought worth measuring, which earlier reports they trusted and how they summarized local conditions. Used critically, the volumes are therefore sources for both regional history and the history of colonial knowledge. Their authority must be disaggregated claim by claim rather than either accepted wholesale or dismissed wholesale.

59.16 The district gazetteer became a durable administrative archive

Early twentieth-century district gazetteers consolidated decades of surveys, settlement reports, censuses and departmental statistics into compact reference volumes. Darbhanga, Muzaffarpur, Monghyr and Bhagalpur gazetteers contain chapters on physical geography, history, population, agriculture, industry, communications, education, health and administration. They are especially valuable for tracing institutional change because compilers frequently summarized earlier conditions before describing the present. Yet the gazetteer is a retrospective synthesis, not a contemporary source for every period it mentions. Where it recounts eighteenth- or early nineteenth-century society, the underlying source must be identified whenever possible. For its own early twentieth-century administrative world, by contrast, it is primary evidence of what the government officially knew and how it organized that knowledge.

59.17 Gazetteers intertwined ethnography with practical governance

The gazetteer's social descriptions sat beside roads, ferries, schools, police stations and land systems because colonial administration treated knowledge as practical infrastructure. A district officer needed a portable account of terrain, population, customary institutions and economic resources. Ethnographic paragraphs therefore acquired an official afterlife: later administrators could repeat classifications first assembled by earlier surveyors. Repetition could harden a tentative observation into an apparent fact, especially when citations were omitted. Historians should track this textual genealogy. If the same statement appears in a 1907 gazetteer and an 1870s statistical account, it may represent one inherited observation rather than two independent confirmations. Administrative continuity is itself historically important, but it must not be mistaken for independent evidence.

59.18 Risley's ethnographic programme sought a more systematic taxonomy

Herbert Hope Risley's *Tribes and Castes of Bengal*, published in the early 1890s, represented a more ambitious attempt to systematize social classification. The work combined an ethnographic glossary with anthropometric data and drew on district information, questionnaires and local reports. Risley treated caste not merely as a list of names but as a structure to be classified and compared. That programme deeply influenced later discussions because it connected administrative enumeration to a theory of social hierarchy and physical type. For modern historical use, its rich descriptive material must be separated from its theoretical apparatus. Kin terms, customs and local names can preserve evidence unavailable elsewhere, while racial and anthropometric interpretations belong to a now-discredited framework and cannot be treated as biological explanations of social history.

59.19 Anthropometry attempted to turn social hierarchy into bodily measurement

The anthropometric component of Risley's work measured physical traits and sought correlations between bodily indices, race and caste rank. Such reasoning reflects late nineteenth-century racial science rather than a valid biological account of Indian social structure. Its historical significance lies in what the state and learned institutions attempted to measure, the procedures they devised and the authority numerical measurement claimed. The presence of a decimal or index gave a speculative racial theory the appearance of precision. For this volume, anthropometric tables are therefore evidence about colonial knowledge-making, not evidence that caste groups possessed fixed racial essences. This distinction also protects regional social history from a false move in which administrative categories, social rank and biological ancestry are collapsed into one supposedly objective hierarchy.

59.20 Social precedence made ranking itself a field of inquiry

Risley and census officials also experimented with arranging caste groups by "social precedence." Such ranking required criteria and local testimony: who accepted food or water from whom, which groups claimed particular ritual status, how Brahmanical opinion was reported, and how competing claims were reconciled. The exercise did not simply discover a single ladder waiting to be written down. Rank could vary by locality, context and informant, and communities could contest official placement. The methodological lesson is not that hierarchy was unreal; hierarchy powerfully shaped social relations. It is that the published order was an administrative synthesis of multiple, sometimes conflicting status practices. The hierarchy in a census report is therefore itself a historical event in the politics of classification.

Classification could feed back into social action

Administrative categories could become consequential without being identical to lived identity.

*Figure 234 — Classification as a feedback loop between society and the state***59.21 Local intermediaries were indispensable to ethnographic classification**

District officers lacked the linguistic range, local genealogical knowledge and everyday access needed to classify populations unaided. They relied on subordinate officials, schoolmen, pandits, maulvis, zamindari staff, community spokesmen and other informants. These intermediaries brought their own intellectual frameworks and social interests to the process. A classification could therefore contain genuine local knowledge while also privileging the perspectives of literate and institutionally connected groups. The archive rarely represents every social stratum equally. The most marginalized could be described by others rather than speaking through their own texts. Recognizing this asymmetry helps explain why administrative ethnography must be compared with petitions, court records, oral traditions and vernacular publications when reconstructing self-description.

59.22 Communities could use the classificatory state strategically

Once census and ethnographic categories acquired public authority, communities had incentives to influence them. Petitions, memorials, genealogies and claims to revised rank formed part of a wider nineteenth- and early twentieth-century politics of representation. A community could emphasize a preferred name, origin narrative, occupation or ritual practice in order to seek recognition. Such activity should not be dismissed as mere fabrication. It shows that classification had consequences and that people understood the state's categories as a resource to be negotiated. At the same time, a successful administrative label could feed back into later self-understanding. The direction of influence therefore ran both ways: society shaped the census, and repeated census categories could reshape social politics.

59.23 Classification fed back through schools, courts, associations and print

The census was not isolated from other colonial institutions. School textbooks, legal decisions, recruitment practices, municipal representation, newspapers and caste or regional associations could repeat classifications first made authoritative in official publications. A label thereby moved from a schedule into public debate. This feedback is one reason colonial categories mattered even when they simplified lived reality. The effect was not uniform. Some labels remained administrative conveniences; others became organizing terms for associations and political claims. The historian should therefore ask what happened after classification: Was the term used in petitions? Did it appear in print? Did officials employ it in recruitment or policy? Did local writers accept, reject or redefine it? Only this second stage reveals whether a category became socially consequential.

59.24 Grierson's Linguistic Survey created a different classificatory map

George A. Grierson's Linguistic Survey of India, published in multiple volumes from 1903 onward after long preparatory work, classified speech through linguistic comparison rather than caste rank. Volume V, Part II treated the eastern Indo-Aryan "Bihari" and Oriya languages and supplied specimens. The survey is fundamental for the history of Maithili and neighbouring speech forms because it documented grammatical and lexical evidence on a scale not previously assembled by the state. Yet its map too was analytical. Decisions about language versus dialect, boundaries and nomenclature reflected comparative philology, administrative data and the available specimens. The survey should be read as a major scholarly achievement and as a historically situated act of classification, not as a timeless map of immutable linguistic borders.

59.25 Linguistic boundaries rarely coincided with district boundaries

Administrative districts were designed for government, while speech continua followed settlement, migration, rivers, markets and kin networks. Gazetteers themselves sometimes noted linguistic transitions within a district. North and south of the Ganga could show different dominant speech patterns; border tracts could mix forms that later maps assign to separate named languages. This mismatch is methodologically productive. It prevents the history of Mithila, Vajji and Anga from being reduced to modern district lines or to one-to-one language territories. Language data should be located at the smallest scale the source permits and compared across time. A later district majority cannot prove the speech of every village, and a linguistic label recorded in 1901 cannot by itself define a medieval cultural frontier.

59.26 Maithili, Angika and Bajjika require source-specific naming discipline

The present volume treats Maithili, Angika and Bajjika through historically controlled evidence rather than forcing every earlier source into current terminology. Colonial records may use “Bihari,” “Maithili,” “Tirhuti,” local dialect names, Hindi/Hindustani or other labels according to the period and classifier. The correct procedure is to report the source’s terminology, identify the speech area or linguistic features where possible, and then explain how that usage relates to later nomenclature. This protects regional history from two opposite errors: erasing distinct linguistic traditions under an overly broad administrative label, or projecting today’s standardized boundaries into a period when naming conventions and written standards were different. The history of a language name is part of social history, not an obstacle to it.

59.27 Self-description and administrative category must remain analytically separate

A census entry is strongest evidence for how the state recorded a person or household; it is not automatically a complete statement of how that person understood identity. Self-description can be recovered more directly from petitions, letters, associations, inscriptions, genealogies, literary texts, community histories and oral testimony, though each has its own limits. The most reliable reconstruction compares the two domains. Agreement between self-naming and administration can show institutional consolidation; disagreement can reveal translation, resistance or competing vocabularies. This distinction is especially important when later political identities are at stake. Historical analysis gains precision when it asks “who used this name, in what document, for what purpose, and at what date?” rather than assuming that one label has always meant the same thing.

Chronology firewall: do not project later labels backward

Figure 235 — Evidence firewall against retrospective social classification

59.28 Colonial classifications are evidence with defined limits

Used carefully, surveys and censuses can establish a great deal: the categories administrators employed; approximate population structures; the distribution of reported occupations; literacy and schooling; language naming; migration and birthplace; institutional locations; and contemporary arguments about status. They are much weaker for proving deep antiquity, biological ancestry, fixed cultural essences or a single consensual hierarchy. Gazetteer statements about origins often repeat tradition or earlier scholarship and require independent corroboration. Census numbers can be compared across decades only after checking changes in definitions and boundaries. These source limits are not reasons to abandon colonial statistics. They are the conditions that make the statistics historically meaningful rather than deceptively exact.

59.29 Śrottriya chronology is protected by a specific Panji-based firewall

This project applies a governing chronological correction to the category Śrottriya. It does not project Śrottriya as a fixed Maithil Brahmin sub-caste into the medieval period. The adopted Panji and Śākhā-pustak chronology places the emergence of Śrottriya as a distinct sub-caste around c. 1800. Nineteenth- and early twentieth-century surveys, censuses, ethnographies or gazetteers can therefore document colonial-era usage, status claims and administrative classification, but they cannot be carried backward as proof of a medieval sub-caste. If a colonial source uses the term, the statement is dated to that source. Earlier social organization must be reconstructed from earlier evidence. This firewall exemplifies the wider method of the volume: later administrative clarity must never substitute for period evidence.

59.30 Conclusion: categories were historical processes as well as historical data

Colonial surveys did not encounter a society without names, ranks, languages or communities, but they changed the scale, form and consequences of naming. Buchanan-Hamilton's broad district inquiries, Hunter's statistical compilations, the 1872 and 1881 censuses, Risley's ethnographic and anthropometric programme, Grierson's linguistic survey and the district gazetteers progressively turned local descriptions into comparable administrative knowledge. The process involved officials and local informants, standardization and contestation, observation and theory. Its archive is indispensable for the nineteenth and early twentieth centuries if each category is kept attached to its date, compiler and purpose. The safest historical question is therefore not "what was this community really?" in an abstract sense, but "how was it described, by whom, under which institutional rules, and how did that description change social action?"

Table 59.1 — Colonial classification sources: evidentiary value and limits

Source / institution	What it can establish	Main interpretive caution
Buchanan-Hamilton district surveys, 1807–14	Early nineteenth-century local descriptions of land, work, institutions, language and social names.	Breadth is exceptional, but observation, local testimony and estimation are mixed; do not project entries backward.
Hunter statistical accounts and district gazetteers	Administrative synthesis of population, economy, institutions and earlier reports at district scale.	Repeated statements may derive from one earlier source; later synthesis is not independent proof for earlier periods.
1872 and 1881 censuses	Enumerated population, reported caste/religion/language, occupation, birthplace and literacy under stated rules.	Definitions, boundaries and compilation changed; final tables hide translation and aggregation decisions.
Risley ethnography	Contemporary social names,	Anthropometric racial explanations

Source / institution	What it can establish	Main interpretive caution
and anthropometry	customs, status claims and the history of colonial racial/ethnographic theory.	are obsolete; ranked administrative syntheses are not timeless social ladders.
Grierson linguistic survey	Comparative linguistic evidence, specimens and historical naming of eastern Indo-Aryan speech forms.	Language/dialect boundaries are analytical and need not coincide with district or modern political boundaries.
Panji, petitions and self-authored materials	Period-specific self-description, genealogy, claims and internal naming practices.	Each source has its own institutional bias; use dated evidence to test rather than merely repeat colonial categories.

Chapter 60 — Education under Colonialism

Colonial education transformed the institutional ecology of Mithila, Vajji and Anga by linking schools, examinations and credentials to a growing public and professional labour market. The change was cumulative rather than substitutive. Sanskrit *ṭols*, vernacular schools, *maktabs*, *madrasas* and household learning persisted while government schools, aided institutions, colleges and university examinations expanded. This chapter traces that layered transition from the early nineteenth-century surveys to Patna University in 1917, with special attention to language, access, patronage, gender and the economic value of credentials.

60.1 Colonial education was a layered institutional transition

Education under colonialism did not begin with an empty landscape and did not proceed as a single replacement of “traditional” learning by English schools. Mithila, Vajji and Anga already contained Sanskrit scholarly institutions, elementary schools, *maktabs*, *madrasas*, household teaching and occupational transmission. The colonial period added new layers: government schools, inspection, grants-in-aid, prescribed curricula, public examinations, colleges and eventually a regional university. Older institutions adapted unevenly rather than disappearing at once. A socio-economic history therefore asks how access, language, credentials, patronage and employment changed. The decisive transformation was not simply the arrival of English; it was the growth of an educational bureaucracy that increasingly linked recognized schooling to examinations, certificates and salaried occupations.

60.2 Indigenous learning remained visible in early nineteenth-century surveys

Before the education department acquired dense statistical returns, district surveys and later William Adam’s inquiries recorded a diverse field of local instruction. Elementary teaching could take place in modest premises with small groups, flexible calendars and locally supported teachers. Sanskrit learning depended on scholarly lineages and patronage; Muslim education ranged from Qur’anic instruction to advanced Arabic and Persian learning. These institutions differed greatly in curriculum, duration and social reach, so they should not be collapsed into one “indigenous system.” Their historical importance is that colonial schooling developed in relation to an existing educational ecology. Some institutions continued outside state recognition, some accepted aid, some changed curriculum, and others lost relative importance as public employment increasingly rewarded new forms of literacy and certification.

60.3 *Ṭols*, *pāṭhśālās*, *maktabs* and *madrasas* served different educational purposes

The labels used in colonial reports describe institutions with distinct functions. Sanskrit *ṭols* could sustain advanced textual study in grammar, logic, law or philosophy and were closely connected to learned reputations and patronage. *Pāṭhśālās* generally served elementary or practical literacy and numeracy in local settings, though curriculum varied. *Maktabs* provided elementary Muslim instruction and *madrasas* could support more advanced Arabic or Persian learning. Household tutors and religious specialists added further channels. These forms did not constitute a single ladder leading to a common examination. Colonial administration increasingly judged them against standardized categories of primary, middle, secondary and collegiate education. The shift in institutional vocabulary itself marks a transformation: learning came to be measured by grades, inspected schools, prescribed subjects and progression toward formal credentials.

60.4 William Adam's reports of 1835–38 are crucial evidence and require caution

William Adam submitted reports on vernacular education in Bengal and Behar in 1835, 1836 and 1838, with the third report including substantial discussion of Bihar. His inquiries remain among the most important early attempts to describe local educational institutions before later departmental standardization. They document teachers, schools, subjects, languages and the uneven social distribution of instruction. Yet Adam's figures are not a modern census of schooling. His evidence combined surveys, samples, official material and estimation, and the category "school" itself did not always correspond to later departmental definitions. The reports are therefore best used to reconstruct forms and relative patterns rather than to manufacture false precision. Their greatest value is to show that vernacular and learned education already had institutional depth when the colonial government began debating a more interventionist policy.

60.5 School attendance, literacy and learned expertise were different measures

Colonial statistics gradually generated counts of schools, pupils, literate persons and examined candidates, but these measures should not be treated as interchangeable. A person could acquire reading, accounting or religious knowledge outside a recognized school; intermittent attendance could produce practical literacy without completion; advanced Sanskrit or Arabic learning did not always fit departmental categories; and census literacy depended on the question and standard used. Conversely, enrolment did not guarantee sustained attendance or mastery. The history of education therefore requires an evidence firewall similar to that used for famine and census classification: institutional counts establish the scale of recognized schooling, examination results measure one form of certified attainment, and census literacy measures a separate administrative category. None alone captures the full distribution of knowledge.

Education under colonialism was a layered ecology, not a simple replacement

Figure 236 — The layered educational ecology under colonialism

60.6 The Anglicist–Orientalist controversy concerned patronage, language and educational purpose

The famous early nineteenth-century debate over education was not simply a quarrel about whether Indians should learn English. It concerned the use of limited public funds, the status of Sanskrit and Arabic learning, the language through which European knowledge should be taught and the intended social audience of state-supported education. Existing institutions of oriental learning already received public patronage, while advocates of English sought to redirect resources toward European literature and science. These policy arguments mattered for Bihar because government institutions and grants operated within the same Bengal Presidency framework. They also altered the employment value of languages. Persian had long been important in administration; English increasingly became a route to higher government and

professional opportunity, even while vernacular literacy remained indispensable for mass schooling and local communication.

60.7 Macaulay's Minute of 1835 gave ideological force to English higher education

Thomas Babington Macaulay's Minute of 2 February 1835 argued for using public educational funds to promote European learning through English rather than sustaining the existing pattern of state-supported Sanskrit and Arabic instruction. Governor-General William Bentinck's decision in March endorsed the new direction. The policy's practical effects were gradual and mediated by existing institutions, finances and local demand. It did not instantly turn village schooling into English-medium education. Its strongest long-run effect was at the upper end of the educational hierarchy, where English increasingly became the language associated with advanced secular curriculum, university examinations and government employment. The distinction between higher English education and vernacular elementary education became a recurring feature of the colonial system.

60.8 Patna School shows that vernacular instruction remained part of early policy

Macaulay's collected educational minutes include a specific 1835 discussion of the Patna School. He approved providing a competent moonshee for vernacular instruction and proposed use of the monitorial or Lancastrian method if one teacher could not directly teach all pupils. This local evidence complicates any claim that the 1835 settlement simply abolished vernacular education. Even within the Anglicist policy environment, administrators distinguished the language and method appropriate to different levels and institutions. Patna thus offers an early example of the hybrid colonial school: English-oriented policy at the top, vernacular teaching within the institution, and imported pedagogical techniques designed to expand instruction cheaply. The combination anticipated later efforts to standardize classrooms while containing per-pupil expenditure.

60.9 Changing official languages altered the economic value of education

Educational demand was shaped by labour markets. As English expanded in higher administration and law, knowledge of English could provide access to clerical, teaching and professional occupations. At the same time, the replacement of Persian in many official functions weakened one established route to state employment, although Persian and Urdu continued in cultural, legal and educational settings. Families therefore faced practical decisions about which languages and curricula justified fees, travel and lost household labour. This helps explain why educational change was socially uneven. A curriculum gained value not only because of intellectual content but because government offices, courts, railways, schools and later professions rewarded particular credentials. Colonial education thus created a new relationship between language learning and salaried work without eliminating older forms of scholarship.

60.10 Wood's Despatch of 1854 supplied the blueprint for a graded system

Despatch No. 49 of 19 July 1854, commonly known as Wood's Despatch, set out a broad programme for expanding education in India. It called for provincial education departments, universities, teacher training, continued government institutions, new middle schools, greater attention to vernacular and indigenous elementary schools, grants-in-aid and support for female education. English was associated with higher branches, while vernacular languages were to serve lower levels and wider access. The significance of the

Despatch for Mithila, Vajji and Anga lies in institutional architecture. Education increasingly became a regular department of government with inspectors, budgets, returns and recognized school grades. Local initiatives could be drawn into this structure through aid, while remaining subject to curricular and inspection rules.

Figure 237 — Educational policy and institutional milestones, 1813–1917

60.11 The Department of Public Instruction made schooling measurable and inspectable

After the mid-century reforms, Directors and Inspectors of Public Instruction helped convert education into a recurring administrative routine. Schools were classified, inspected and reported; enrolment, attendance, expenditure, teacher qualifications and examination performance entered annual returns. This created an archive far denser than the earlier descriptive surveys. It also changed institutions themselves. A school seeking recognition or aid had incentives to maintain registers, follow prescribed curricula and present pupils for examinations. Educational statistics therefore record both reality and policy effects: the state measured schools, and schools adapted to what the state measured. For historians, departmental reports can reconstruct institutional growth, but unrecognized teaching must be sought elsewhere because it could fall outside the official statistical field.

60.12 Grants-in-aid connected private initiative to public standards

The grant-in-aid system allowed government funds to support schools managed by municipalities, missions, associations, landed patrons or other private bodies. It expanded capacity without requiring the state to own every institution. The arrangement also became a mechanism of regulation. Eligibility could depend on inspection, accounts, attendance, curriculum and examination results. Financial responsibility was therefore shared, but administrative standards increasingly came from the education department. In Bihar this structure was important because regional educational growth depended heavily on local philanthropy and institutional initiative. The resulting system was neither fully state-run nor purely private. It was a negotiated public-private order in which money, recognition and examination rules bound diverse schools to a common bureaucratic framework.

60.13 Vernacular primary schooling and English higher schooling formed an unequal ladder

The graded colonial system formally recognized vernacular elementary education as the route for the wider population while English acquired increasing importance at higher stages. In principle this could extend basic learning without requiring English for every child. In practice, the ladder was unequal. Advancement toward secondary school, entrance examinations and college often required resources that poorer rural households lacked, and English competence became a gate to the most prestigious credentials. The structure therefore widened education while also producing new forms of stratification. A village child could enter a recognized primary school yet remain far from the institutional pathway that led to college. The social history of education must consequently examine transitions between levels, not simply total enrolment.

60.14 Curriculum and examination reorganized educational time

Recognized schools increasingly worked through timetables, graded classes, prescribed textbooks and examinations. These practices altered the rhythm of learning. Older institutions could organize teaching around mastery of texts, seasonal attendance or individualized progression; departmental schools required a more standardized calendar and comparable attainment. Examinations also created strong incentives to teach toward defined syllabi. This could support curricular consistency and mobility between institutions, but it could narrow what counted as educational success. The new temporal discipline mattered economically as well. Regular attendance conflicted with agricultural cycles, household work and artisanal labour, especially for poorer children. Thus the classroom timetable was not a minor administrative detail: it redistributed children's time between household production and certified learning.

60.15 Teacher training sought to standardize pedagogy

Wood's Despatch and later educational policy emphasized training institutions for teachers. Normal schools and training classes attempted to produce instructors familiar with graded curricula, classroom management and monitorial methods. District gazetteers from the early twentieth century record specialized training schools for primary teachers in parts of the region; Monghyr, for example, had third-grade training schools for gurus. The expansion of trained teaching did not eliminate locally learned pedagogy, and many schools continued to employ teachers without formal professional credentials. But the idea of the "trained teacher" created a new occupational standard. Teaching gradually became more closely linked to certification, salary scales and departmental supervision, strengthening the connection between education and a modern public-service labour market.

60.16 District schools expanded access unevenly across space

Educational opportunity depended heavily on geography. A district headquarters or important town could sustain a high school, hostel or specialized institution that was impossible in many villages. Roads and later railways reduced some travel barriers, but distance still imposed costs on rural households. Flood-prone tracts of north Bihar added seasonal mobility problems, while dispersed settlement affected school catchments. District Boards and local bodies became important to primary and middle schooling precisely because location was a local fiscal and administrative problem. The resulting map of education was therefore nodal rather than uniform: towns such as Patna, Darbhanga, Muzaffarpur, Monghyr and Bhagalpur accumulated institutions earlier and more densely than many rural interiors.

60.17 Patna College institutionalized higher education in Bihar from 1863

The institutional genealogy of Patna College reaches back to Patna High School, founded in 1835, and to mid-century attempts to establish collegiate instruction. The present college dates its establishment to 1863 and describes itself as Bihar's oldest institution of higher education. Its importance extends beyond institutional chronology. A durable government college in Patna reduced, though did not remove, dependence on Calcutta for advanced study and created a regional centre for the education of teachers, administrators, lawyers and other professionals. Because admission to collegiate education required prior schooling and examination success, the college also sat at the top of a selective ladder. Its growth made the inequalities of secondary preparation more consequential: access to a college mattered only for those able to reach the threshold.

60.18 Calcutta University made affiliation and examination central to higher education

The university system created after the 1854 Despatch was initially strongly affiliating and examining. Colleges across Bengal and Bihar prepared students for standardized university examinations, while the university supplied credentials recognized across a wide territory. This arrangement promoted a common academic framework but concentrated authority over curriculum and certification. Regional colleges therefore belonged to a network whose institutional centre lay outside Bihar. The examination system shaped school curricula downward because secondary institutions prepared candidates for entrance requirements. It also created a portable credential useful in government and professional employment. The colonial educational order consequently linked a local classroom in Bihar to a presidency-wide hierarchy of examinations, textbooks and degrees.

60.19 T.N.B. College in Bhagalpur strengthened higher education in Anga from 1883

T.N.B. College, Bhagalpur, traces its foundation to 1883. Its establishment gave the Anga region a major centre of higher learning and illustrates the importance of Indian philanthropy in expanding collegiate education. The college developed within the Calcutta University affiliation system and initially served students who otherwise faced longer journeys for advanced study. Bhagalpur's role as a district and commercial centre, and later its railway connections, gave the institution a wider hinterland. The college demonstrates that colonial educational growth cannot be narrated solely through government policy. Local donors, landed elites and civic ambitions created institutions that then entered the public system through affiliation, examinations and recognition. The result was a mixed institutional economy in which private initiative produced public educational infrastructure.

60.20 Darbhanga Raj patronage connected landed wealth to educational modernization

The Darbhanga Raj became an important patron of new educational institutions in Mithila during the late nineteenth century. Studies of the Maharaja period describe support for an Anglo-vernacular school, free or subsidized vernacular schools and attention to Sanskrit, English and female education. Such patronage did more than imitate government. It allowed a landed estate to convert wealth and public prestige into institutions, scholarships and educational access. At the same time, patronage could reinforce the centrality of elite centres and depended on the priorities of the donor. The Darbhanga case therefore belongs to a wider

pattern in which colonial policy created recognized educational forms while Indian landed and urban patrons supplied resources that helped those forms spread regionally.

Figure 238 — The colonial credential ladder and its access filters

60.21 Sanskrit learning persisted and was reconfigured rather than simply extinguished

Mithila's Sanskrit scholarly traditions did not disappear when English colleges expanded. Tols and learned lineages continued to train students, preserve manuscripts and sustain disciplines such as grammar, law, logic and philosophy. Colonial educational policy changed their environment by redirecting prestige, employment and public funding toward new institutions, yet traditional learning could also receive patronage from estates, communities and sometimes government-recognized arrangements. The key historical change was pluralization of credential systems. Scholarly reputation within a Sanskrit network remained meaningful, while school and university certificates acquired increasing value in public employment. Some families therefore combined forms of learning or directed different children toward different educational routes. Continuity and transformation coexisted.

60.22 Muslim educational institutions also adapted to changing linguistic and occupational incentives

Maktabas, Qur'anic schools and advanced Arabic or Persian institutions continued across the region, but the changing language of administration altered their economic environment. Persian retained literary and legal importance even after losing much of its former official role; Urdu/Hindustani, Arabic and English served different institutional purposes. Early twentieth-century district evidence from Monghyr, for example, records aided maktabas, Qur'anic schools, a madrasa and numerous private Arabic or Persian institutions alongside government-recognized schools. This coexistence is methodologically important. "Muslim education" cannot be reduced to one institution or one response to colonial policy. Families negotiated among religious study, vernacular literacy, Persianate learning and the new credential economy according to locality, resources and occupational goals.

60.23 Girls' schooling expanded slowly and exposed the gendered limits of the system

Official policy increasingly endorsed female education, but implementation lagged far behind male schooling. Household concerns about respectability, distance, mixed institutions, age, domestic labour and

marriage could restrict attendance even when a school existed. District gazetteers record small girls' schools and zenana teaching schemes, and they often comment on the slow pace of expansion. The regional imbalance remained severe into the twentieth century. Patna University's own institutional history notes that in 1917 there was not a single girl student in Bihar's colleges and no separate institution of higher education for women in the province. This stark evidence shows that the growth of schools and colleges cannot be equated with gender-neutral access. The colonial credential economy was created long before women could enter it on equal terms.

60.24 Caste, class and community shaped educational opportunity without determining it mechanically

School access depended on household resources, social networks, local prejudice and the distribution of institutions. Elite and prosperous families were better placed to finance prolonged education, hostel residence and English study. Marginalized communities could face economic exclusion and discriminatory practice, while some reformers and public bodies created scholarships or special initiatives. These inequalities should not be converted into a timeless claim that any community was naturally "educated" or "uneducated." Colonial statistics record changing participation under specific institutional conditions. Education itself could become a resource for social mobility and collective organization, so patterns shifted over time. The historical question is how barriers operated, which policies reduced or reinforced them, and how communities responded to the opportunities created by recognized schooling.

60.25 Fees, distance and household labour were practical barriers to attendance

The cost of schooling was larger than the stated fee. Books, clothing, travel, lodging and the value of a child's labour all entered household decisions. Agricultural families needed labour seasonally; artisan households could depend on children's participation in production; poorer urban families required wage contributions. A school located several miles away imposed additional time and safety costs, especially for girls. Fee exemptions, scholarships and local schools could reduce these burdens but not eliminate them. This economic perspective explains why supply-side measures such as opening a school did not automatically produce universal attendance. Education competed with other household claims on time and cash. The unequal ability to absorb those costs helped reproduce class differences inside an expanding educational system.

60.26 Language governance in Mithila and Anga did not simply mirror speech at home

The language of schooling was an institutional choice shaped by textbooks, teacher supply, examination requirements and administrative classification. Local speech in Mithila and Anga did not necessarily coincide with the "vernacular" label used by education officials. A child could speak Maithili or another regional form at home while learning through a standardized school language and later English. Grierson's linguistic work demonstrated the distinctiveness and internal diversity of the eastern Indo-Aryan speech area, but educational administration often operated with broader written categories. This mismatch mattered for comprehension, literacy and cultural authority. It also influenced the later public politics of language. The history of Maithili, Angika and Bajjika in education must therefore distinguish spoken repertoire, literary tradition, official school language and university subject status.

60.27 Education created new clerical and professional labour markets

The expansion of courts, revenue offices, municipalities, railways, schools and commercial firms created demand for literate employees. Secondary and collegiate education supplied clerks, teachers and candidates for professional training, while examinations helped employers screen applicants. This labour-market connection gave families a concrete reason to invest in schooling. It also created credential inflation: once certificates became common for particular posts, informal literacy alone lost competitive value. The educational system therefore changed the social meaning of knowledge. Learning was still pursued for religion, scholarship and personal cultivation, but recognized schooling increasingly carried an exchange value in the salaried economy. This was one of the most durable socio-economic effects of colonial education.

Regional institutions were tied into a wider examination and credential network

Figure 239 — Regional educational nodes within the wider examination network

60.28 Schools and colleges helped create new publics and associations

Educational institutions gathered students from different localities, exposed them to common curricula and linked them through alumni, debating societies, newspapers and professional networks. These settings contributed to the formation of a new public sphere in which regional interests, social reform and politics could be discussed. The process was not confined to English education: vernacular print and local associations were equally important. Colleges in Patna and Bhagalpur and educational patronage in Darbhanga helped create concentrations of literate actors who participated in civic and political life. This chapter stops short of the detailed history of print culture, which belongs to Chapter 61, but the institutional connection is essential: schools produced readers, writers, teachers and organizers who enlarged the audience for print and public argument.

60.29 Patna University in 1917 marked a regional consolidation of higher education

The establishment of Patna University in 1917 gave Bihar its own university structure after decades in which its colleges operated within the Calcutta-centered system. Initially the new university inherited the affiliating and examining logic characteristic of Indian universities, but its creation was institutionally significant. It brought the regulation of colleges, examinations and degrees closer to Bihar's educational network and symbolized a regional claim to intellectual infrastructure. The university's own history also preserves evidence of the limitations of the moment: women were absent from Bihar's colleges in 1917, and hostel residence could still encounter caste-based anxieties among male students. Institutional consolidation therefore did not mean social democratization. It created a platform whose expansion and contestation would continue in the twentieth century.

60.30 Conclusion: colonial education expanded credentials without erasing older knowledge

Between the early nineteenth century and 1917, education in Mithila, Vajji and Anga changed from a plural field of locally sustained institutions into a more densely interconnected system of indigenous learning, government schools, aided institutions, district boards, colleges and university examinations. Adam's reports reveal the pre-existing vernacular ecology; the 1835 policy turn privileged English at higher levels; Wood's Despatch supplied an administrative blueprint; later commissions strengthened inspection, grants and local responsibility; Patna College, T.N.B. College and Darbhanga patronage regionalized higher and secondary education; and Patna University consolidated the credential network. The transformation widened access but remained sharply unequal by gender, class, locality and social position. Its lasting innovation was the power of recognized credentials, not the disappearance of older intellectual traditions.

Table 60.1 — Evidence for colonial education: what each source can and cannot establish

Source / institution	What it can establish	Main interpretive caution
Adam's reports, 1835–38	Forms, languages, teachers and distribution of vernacular and learned education before mature departmental statistics.	Survey and estimation methods differ from later school censuses; “school” and “literacy” are not fixed categories.
Macaulay/Bentinck policy, 1835	Shift of state patronage toward English and European learning at higher levels; local evidence such as Patna School.	Do not infer an immediate abolition of vernacular or older institutions.
Wood's Despatch, 1854	Blueprint for education departments, universities, teacher training, grants-in-aid, vernacular elementary and English higher instruction.	Policy design is not proof of uniform implementation across districts.
Education Commission, 1882–83	All-India review of primary and secondary education, indigenous schools, grants, teachers, girls' education and administration.	Provincial and local conditions varied; recommendations must be separated from achieved results.
Patna College / T.N.B. College / Darbhanga patronage	Regional institutionalization of secondary and collegiate education and mixed government-private finance.	Institutional founding dates do not measure the social reach of higher education.
District gazetteers and Patna University history	Early twentieth-century school types, teacher training, female education, recognized/unrecognized institutions and regional consolidation.	Administrative recognition omits some informal teaching; institutional narratives may be retrospective.

Chapter 61 — Print Culture

Print culture changed the social life of texts in Mithila, Vajji and Anga by making arguments, reports, literary works and linguistic claims reproducible across distance. It did not erase manuscript or oral transmission. Instead, presses, lithography, schools, postal systems, railways, journals and associations created a denser communication environment in which English, Hindi, Urdu, Maithili and Sanskrit occupied overlapping but unequal positions. This chapter follows that transformation from the nineteenth-century press regime to the early twentieth-century Maithili periodical world, with particular attention to script technology, multilingual readership, regulation, circulation and the making of regional publics.

61.1 Print culture was an institutional ecology, not a single technological event

Print entered Mithila, Vajji and Anga through a layered ecology of presses, paper, type, lithography, editors, schools, postal routes, railways, booksellers and readers. It is therefore misleading to describe colonial print as a simple moment when manuscripts were replaced by books. The social effects of print depended on who could finance publication, which scripts could be set economically, where presses were located, how copies travelled, and which institutions taught people to read them. Calcutta remained a crucial publishing centre for much of eastern India, while Patna, Bhagalpur, Darbhanga and other towns gradually developed their own printing and journalistic capacities. Print expanded the reproducibility of texts and the speed with which arguments could circulate, but the new medium remained embedded in older practices of recitation, copying, commentary and collective reading. For this reason, the chapter treats print as an additional infrastructure of social communication rather than as a technological rupture.

61.2 Manuscript, oral and printed transmission continued to coexist

The persistence of manuscript culture is especially important in Mithila. Sanskrit scholasticism, Panji records, ritual manuals, genealogical materials, songs and literary texts had long circulated through handwritten copies, memorisation and performance. Printed editions could stabilize one version and multiply it, but they did not automatically supersede manuscript authority. A scholar might teach from a handwritten text while consulting a printed edition; a family might preserve a genealogical manuscript while reading printed journals; songs printed in periodicals could continue to circulate primarily through performance. Print therefore altered the scale of reproduction without eliminating the social situations in which texts acquired meaning. This coexistence also warns against using first print dates as dates of composition. A work printed in the nineteenth or twentieth century may preserve material considerably older than its edition, while the editorial choices of the printer may themselves be modern. The history of print must consequently keep composition, manuscript transmission, oral circulation and publication analytically distinct.

61.3 Calcutta functioned as an external publishing metropolis for Bihar and Mithila

For much of the nineteenth century, the most developed printing infrastructure available to writers and organisations in Bihar lay outside the region, above all in Calcutta. The Bengal Presidency connected North Bihar and Anga administratively and commercially to the metropolis, and books or newspapers intended for readers in Bihar could be composed, financed or edited locally yet printed in Calcutta. This spatial separation matters. A publication's imprint may identify the place of printing rather than the social geography of its authors or readership. The example of Bihar Bandhu is instructive: histories of Hindi journalism place its

beginning in Calcutta in 1872 and its press in Patna from 1874. Such trajectories show that regional print cultures often developed through metropolitan facilities before acquiring local presses. The movement of proofs, manuscripts and finished copies between Calcutta and Bihar also linked literary production to postal and transport systems. Print geography therefore cannot be reduced to the location named on a title page.

61.4 Government, missionary and commercial printing created different textual markets

Colonial printing did not have a single sponsor. Government presses produced regulations, reports, forms, gazetteers, educational materials and statistical publications. Missionary presses elsewhere in the Bengal sphere demonstrated the value of printing for religious translation, literacy and schooling. Commercial printers responded to demand for textbooks, almanacs, religious books, literary works, newspapers, invitations and administrative stationery. These sectors overlapped but operated under different incentives. Government printing favoured standard forms and archival reproducibility; missionary printing linked text to pedagogy and proselytisation; commercial presses depended on paying markets, patrons and subscriptions. Local landed patrons and associations could subsidise publications that would not survive on sales alone. The resulting print field was therefore heterogeneous. A district report, a Maithili magazine, a Hindi newspaper, an Urdu lithographed tract and a Sanskrit edition might share paper and distribution networks while serving very different audiences. Reconstructing print culture requires following these distinct institutions rather than treating every printed object as evidence of the same readership.

61.5 Type, script and cost were social constraints on what could be printed

Movable type made repeatable composition possible, but every script required fonts, matrices, compositors and conventions of spelling. Where a usable typeface was unavailable or expensive, publication could be delayed, shifted to another script, or produced through lithography. These technical constraints had cultural effects. They could privilege scripts already supported by large printing markets and educational institutions. In North India, the growing infrastructure of Devanagari interacted with Hindi and Sanskrit printing, while Perso-Arabic scripts benefited from lithographic practices suited to calligraphic forms. Mithilakshar or Tirhuta possessed deep manuscript prestige in Mithila but entered a print environment in which ready type and trained compositors were far less available. The later predominance of Devanagari in Maithili print must therefore be explained through printing economics, schooling and institutional networks as well as literary choice. Script change was not a simple referendum on cultural value.

Figure 240 — Print ecosystem in colonial Mithila-Vajji-Anga

61.6 Lithography helped preserve manuscript-like visual forms in Urdu and Persian print

Lithography, which reproduced writing from a prepared surface rather than requiring every character to be assembled from movable type, was particularly important for languages written in Perso-Arabic scripts. It allowed calligraphic styles familiar from manuscripts to enter print with fewer typographic compromises. In Bihar, where Urdu and Persian remained important languages of learned, legal and public communication during the nineteenth century, this technology helped sustain a print culture that did not visually resemble Nagari typography. The technological diversity of colonial print therefore paralleled linguistic diversity. Newspapers, official notices, poetry and religious texts could move through different production systems even within the same town. This matters for archival survival: lithographed works may be catalogued differently from typographic books, while cheap ephemera often disappeared. A history based only on surviving bound books risks underestimating the density of short-lived pamphlets, announcements, calendars and newspapers that once circulated.

61.7 Patna's early Urdu press shows that print history in Bihar was multilingual from the start

Regional histories commonly identify Patna Harkara, associated with Sah Abu Torab and dated to 1855, as one of the earliest newspapers published from Patna, and they record Akhbar-e-Bihar in 1856. The surviving documentation for these early titles is uneven, so their exact chronology should not be made to carry more weight than the evidence permits. Their larger significance is clearer: Urdu was central to Bihar's early newspaper world. That fact complicates narratives that begin regional print history with Hindi or English alone. The transition from Persian in administration, the continuing cultural reach of Urdu, and the emergence of Hindi public writing produced overlapping rather than sequential spheres. Readers could encounter more than one language, and writers often moved among linguistic registers. The multilingual character of the press is therefore a starting condition of colonial Bihar's print culture, not a later complication.

61.8 The Press and Registration of Books Act of 1867 made print more legible to the state

The Press and Registration of Books Act of 1867 required formal information about printers, publishers and places of printing and created mechanisms for preserving copies of publications. Its administrative logic is central to the archive historians now use. By compelling declarations and imprint information, the law made printed production more traceable than much manuscript circulation had been. The same visibility that aids historical research also served regulation. A printed statement could be connected to a responsible printer or publisher, and the state could count, classify and monitor the expanding press. The act therefore illustrates the double character of colonial information systems: they preserved evidence while increasing administrative oversight. Lists of presses and publications should be read as records produced within this regulatory environment, not as neutral inventories of everything people read. Unregistered, ephemeral or privately circulated material remains much harder to recover.

61.9 Bihar Bandhu linked Hindi journalism to a growing regional public

Bihar Bandhu, founded in 1872 and associated with Balakrishna Bhatt and Keshavram Bhatt, is a major landmark in the growth of Hindi journalism connected with Bihar. Accounts of the paper note that it began publication in Calcutta and that its press moved to Patna in 1874. This movement captures a wider transition from dependence on metropolitan printing to a more locally rooted newspaper infrastructure. Bihar Bandhu also participated in debates over the language of courts and public administration, demonstrating that a newspaper could become an instrument for linguistic advocacy as well as news. Yet the paper's Hindi identity should not be projected onto the whole population. Newspaper readership remained concentrated among literate groups, and the language of print could differ from everyday speech in Mithila, Vajji and Anga. Its importance lies in the creation of a repeatable public forum through which language claims, reforms and regional interests could be articulated and circulated.

61.10 The Bihar Herald added an English-language public to the regional press

The Bihar Herald, founded in Patna by Guru Prasad Sen in 1875, became an important English-language newspaper in Bihar. English papers served several overlapping publics: officials, lawyers, teachers, students, professionals and politically active readers who used English to address the colonial state or communicate beyond a single vernacular constituency. The existence of an English regional press did not make it socially detached from local questions. English newspapers could argue for administrative reform, public works, representation or provincial interests precisely because English gave access to officials and wider imperial networks. The coexistence of English with Hindi and Urdu journalism also created asymmetries. A claim framed in English could circulate through a different administrative and professional audience from the same claim framed in a vernacular. Print culture therefore multiplied publics rather than creating one unified public sphere.

61.11 The Vernacular Press Act of 1878 exposed the political inequality between languages

The Vernacular Press Act of 1878 subjected Indian-language newspapers to coercive powers not imposed in the same form on the English-language press. Whatever its varying local enforcement, the law made linguistic medium itself politically consequential. A newspaper's language could determine its legal vulnerability. This asymmetry is essential for understanding regional print. Vernacular journalism was not simply a cheaper or more accessible counterpart to English journalism; it operated under a distinct regulatory

threat at a moment when criticism of colonial policies was expanding. The act was repealed in 1882, but its short life demonstrated the colonial state's capacity to discriminate among printed publics. In a multilingual province, censorship therefore interacted with language politics. Editors had to consider not only what they said but the legal environment attached to the language in which they said it.

Figure 241 — Selected milestones in the regional print environment, 1835–1910

61.12 Repeal in 1882 did not end surveillance of printers and newspapers

The repeal of the Vernacular Press Act under Lord Ripon in 1882 removed one notorious form of language-specific control, but it did not create an unregulated press. Registration requirements, criminal law, sedition provisions and later press legislation remained available to the colonial state. Printing presses were visible businesses with named proprietors, addresses and equipment. Newspapers depended on postal carriage and could be watched through official translation and intelligence systems. The history of print freedom must therefore be written as a changing balance of permissions, liabilities and enforcement rather than as a simple alternation between censorship and liberty. This regulatory background shaped regional journalism even when a particular paper was not prosecuted. The possibility of seizure, security demands or criminal proceedings affected investment and editorial risk, especially for small publications with little capital.

61.13 Grierson's 1881 Maithili grammar turned linguistic description into a reproducible scholarly object

George A. Grierson's *An Introduction to the Maithili Language of North Bihar*, first published through the Asiatic Society in 1881, is an important moment in the print history of Maithili. Its significance is not that Maithili suddenly became a language because it was described in print; the language and its literary traditions long predated the publication. Rather, grammar, chrestomathy and vocabulary made a particular description of Maithili reproducible within colonial and scholarly networks. Printed linguistic works could be cited, reviewed, taught from and incorporated into later surveys. They helped stabilize spellings and labels while also subjecting living speech to classificatory frameworks. This chapter therefore treats Grierson's book simultaneously as evidence about Maithili and as an intervention in the history of its public representation. Print gave linguistic description durability and institutional reach beyond the immediate field encounter.

61.14 Textbooks and examinations gave printed norms institutional force

The educational system examined in Chapter 60 created recurring demand for printed textbooks, readers, grammars, dictionaries and examination guides. Once a school adopted a text, its vocabulary, spelling and grammatical categories reached pupils through repeated classroom use. University and school examinations intensified this standardising effect because students were rewarded for reproducing recognized forms. The print market for education could therefore influence language even where the medium of instruction did not match household speech. In Mithila and Anga, Hindi, Urdu, English and Sanskrit all participated in this institutional economy. Maithili's limited position in formal schooling meant that its early modern print sphere developed heavily through literary journals, associations and privately supported publications rather than through a large compulsory textbook market. This difference helps explain why the social history of Maithili print cannot be inferred from literacy statistics alone.

61.15 Hindi–Urdu competition intersected with, but did not absorb, Maithili and Angika speech worlds

Late nineteenth-century North Indian print was shaped by widening Hindi–Urdu competition over script, vocabulary, schooling and official use. Bihar participated strongly in these debates, yet the binary did not map neatly onto everyday language. Large populations in Mithila and Anga spoke Maithili, Angika and other regional varieties while reading or being schooled in standardized Hindi or Urdu. Print could therefore widen the distance between spoken repertoires and public written languages. It could also create new opportunities: readers who mastered Nagari or Perso-Arabic script could participate in wider literary markets beyond their district. A regional history must keep both processes visible. The rise of Hindi print did not prove that Maithili lacked independent linguistic history, and the presence of Maithili speech did not mean that every Maithili speaker demanded Maithili as the language of print. Language choice was conditioned by education, market size, employment, script availability and political strategy.

61.16 Early twentieth-century Maithili journals created a new literary-public infrastructure

The opening years of the twentieth century saw a cluster of Maithili periodicals that provided writers with recurring publication rather than occasional book form. Modern scholarship commonly lists Maithil Hit Sadhan, Mithila Moda and Mithila Mihir among the foundational journals of this phase. They carried poetry, prose, social commentary and linguistic discussion, helping connect authors and readers scattered across different towns. Their importance lay partly in periodicity. A journal could sustain an argument across issues, publish responses, create reputations and train readers to expect regular new writing. It also made literary activity visible as a collective enterprise. The periodicals were not confined to a single linguistic purism; several carried Hindi alongside Maithili, and Mithila Moda also used Sanskrit. The modern Maithili public sphere therefore emerged through multilingual print practices rather than through immediate monolingual standardization.

61.17 Early Maithili periodical dates should be presented with source-aware precision

Secondary sources do not agree perfectly on the first year of every early Maithili periodical. Maithil Hit Sadhan is commonly dated 1905; Mithila Moda appears as 1905 or 1906; and Mithila Mihir is variously given as 1908 or 1909. The later Darbhanga district gazetteer explicitly states that Mithila Mihir had been a popular weekly since 1908, while other histories round or date its launch differently. The correct historical response is

not to conceal the discrepancy but to state it. For chronological analysis, the important fact is the cluster itself: by the first decade of the twentieth century, regular Maithili-oriented periodicals existed and were creating a durable print public. Figure 241 therefore uses ranges where the literature is inconsistent. This practice prevents false precision from becoming a new historical claim.

61.18 Bilingual and trilingual journals reveal readers with overlapping literacies

The coexistence of Maithili, Hindi and sometimes Sanskrit within the same periodical is evidence against imagining sharply bounded readerships. Editors could assume that at least part of their audience crossed language registers, and a single issue could address literary, reformist and scholarly constituencies differently. Bilingual publication also expanded the potential subscription base and enabled a Maithili-oriented journal to intervene in the wider Hindi public sphere. At the same time, multilingualism could reproduce hierarchy if one language was reserved for prestigious genres or formal argument. The page itself became a site where linguistic relationships were negotiated. For historians, this means that counting titles by a single language category may obscure how publications actually functioned. A journal labelled Maithili could contain substantial Hindi material; a Hindi newspaper could report on Maithili-speaking districts; English papers could relay local political claims. Print culture was multilingual in use even when catalogues require one language label.

61.19 Devanagari's rise in Maithili print was technological and institutional as well as ideological

Mithilesh Kumar Jha has emphasized that modern Maithili writers increasingly adopted Devanagari as print expanded, while Mithilakshar or Tirhuta retained historical and symbolic importance. Three practical conditions are especially relevant: modern Tirhuta type was not readily available; Sanskrit scholars in Mithila were already familiar with Devanagari; and wider Nagari promotion supplied fonts, printers and institutional support. These factors did not erase Tirhuta manuscripts, nor did they prove that Devanagari was historically native to every Maithili textual practice. They show how a script with stronger industrial infrastructure can acquire dominance in print. The history is therefore one of media ecology. Manuscript prestige and typographic convenience could point in different directions, and writers had to choose between them when they wanted reproducible, affordable circulation.

Figure 242 — Script and language choices in early modern Maithili print

61.20 Mithila Mihir connected Darbhanga patronage to a long-lived Maithili periodical

The Darbhanga district gazetteer attributes the establishment of the weekly Mithila Mihir to the efforts of the Maharajadhiraj of Darbhanga and describes it as an important opportunity for old and new writers. This patronage illustrates how landed wealth could be converted into cultural infrastructure. A periodical required presses, editors, paper, distribution and the ability to survive uneven subscription income. Patronage could stabilize those costs long enough for a readership to form. Mithila Mihir also became a forum in which rural life, social change, literature and language politics could be represented over decades. Its history therefore links the landed society discussed in Chapter 55 to the cultural modernization of the twentieth century. Patronage did not make the journal merely an elite instrument; the more significant question is how the resource base of an elite institution enabled a wider and eventually more diverse field of contributors and readers.

61.21 Bhagalpur and the Anga region participated in print through education, commerce and communication networks

Anga's print history cannot be reduced to newspapers printed inside Bhagalpur alone. The city was already a major educational and commercial node, and its readers were connected by rail and post to Calcutta, Patna and other publishing centres. Books and newspapers could therefore become locally important without being locally manufactured. The same distinction applies to Monghyr, where district evidence records a dramatic growth of postal communication. In 1906–07 the Monghyr district received more than 2.6 million postal articles, including over 110,000 newspapers. Such figures do not identify individual readers or prove that every paper was read locally, but they demonstrate the physical scale of printed circulation reaching the eastern Bihar corridor. Print culture in Anga was consequently a network phenomenon: production, transport and consumption could occur in different places.

61.22 Post and rail changed the economics and temporality of periodical circulation

A periodical differs from a book partly because delay can destroy its value. News, advertisements, examination notices and political commentary depend on regular delivery. The expansion of postal offices, railway connections and cheaper paper therefore mattered to print culture as much as the press itself. District statistics from Monghyr show how quickly postal volume expanded by the early twentieth century, including a large newspaper component. Railways also connected printing centres to market towns and district headquarters, while postal subscriptions allowed journals to reach readers beyond retail bookshops. These networks reduced the importance of physical proximity to a press. A Maithili reader could subscribe to a journal printed elsewhere; a lawyer in Darbhanga could read a Calcutta English paper; a trader in Bhagalpur could receive commercial news from Patna or Bengal. Print helped synchronize dispersed readers because transport infrastructures made recurring delivery possible.

61.23 Reading rooms, libraries and collective reading widened the social life of a single copy

Circulation figures cannot be equated with readership. One copy of a newspaper might be read by several people in a school, hostel, library, office, tea shop or association. Literate readers could also read aloud to

others. Collective reading was especially significant where household subscriptions were expensive or literacy uneven. Later district gazetteers repeatedly mention public libraries, information centres and reading facilities, evidence of a durable institutional pattern that had roots in the colonial period. These spaces transformed print into conversation. A newspaper article could become the subject of debate, a petition or a meeting without every participant possessing a copy. Historians should therefore resist two opposite errors: assuming that low sales meant negligible influence, and assuming that every circulation number represented a unique reader. The relevant unit is often a reading network rather than an individual subscriber.

61.24 Women entered print culture unevenly as readers, subjects and authors

The gender inequality described for colonial education shaped print as well. Lower female literacy reduced direct access to newspapers and books, while domestic labour, seclusion practices and limited schooling constrained participation in public reading spaces. Yet women were not absent from print culture. Reform debates frequently made female education, marriage and household conduct subjects of publication, and literate women gradually appeared as readers and writers. Printed religious texts, songs, domestic manuals and literary works could enter households even where women did not participate in formal associations. Oral reading also mediated access. Because surviving newspapers were largely edited and written by men, the archive overrepresents male voices. A responsible social history distinguishes between women as objects of reform discourse and women as producers or interpreters of print. The two categories should not be collapsed.

61.25 Caste and class shaped access to print without making readership socially fixed

Printing reduced the cost of reproducing a text compared with hand copying, but it did not eliminate inequality. Schooling, disposable income, leisure, language competence and proximity to distribution all influenced who could read regularly. Educated upper and middle groups were therefore disproportionately represented among editors, correspondents, subscribers and association leaders. Caste networks could finance journals, circulate marriage or genealogical information, and mobilise reform. At the same time, expanding schools, cheap newspapers and collective reading could bring print to groups previously underrepresented in manuscript scholarship. The social composition of readership changed over time. The key methodological point is that a printed claim made by an elite association cannot automatically be treated as the voice of an entire caste, language community or region. Print makes claims visible; it does not by itself prove representativeness.

61.26 Newspapers and journals helped associations turn local grievances into regional claims

Associational life and print reinforced one another. Meetings generated resolutions, reports and petitions; newspapers publicised them; readers responded; and subsequent meetings could cite the published discussion as evidence of wider support. This feedback loop was important in campaigns over language, education, employment and provincial administration. Bihar's English and Hindi newspapers participated in arguments for a distinct provincial identity separate from Bengal, while Maithili journals increasingly articulated cultural and linguistic claims centred on Mithila. Print did not create these interests from nothing, but it gave them repeatable wording and wider geographic reach. A slogan or resolution could travel beyond the town in which it was first formulated. In this sense, print converted local organisation into a networked public claim.

61.27 Printed descriptions helped redefine “Mithila” as a modern public region

The meaning and spatial extent of Mithila had never depended on one administrative boundary, and colonial districts did not map perfectly onto older cultural geographies. Print nevertheless gave writers new tools for arguing about the region. Historical essays, literary histories, journals, maps, genealogical discussions and language advocacy could repeatedly name “Mithila,” identify its cultural features and debate its borders. This recurrent naming helped produce a modern regional public that was connected but not identical to older ritual or political concepts of Videha and Tirhut. The process was contested: different authors emphasised language, caste networks, sacred geography, political administration or literary inheritance. Print amplified those disagreements rather than resolving them. The historian should therefore treat printed regionalism as evidence of active boundary-making, not as proof that one timeless territorial definition had always existed.

Figure 243 — Print circulation as a feedback loop

61.28 The Indian Press Act of 1910 restored stronger coercive powers at a nationalist moment

By the opening decade of the twentieth century, print had become central to nationalist organisation across India. The Indian Press Act of 1910 gave governments strong powers to demand securities and forfeit publications or printing property in cases judged seditious. For small regional presses, financial penalties were particularly consequential because a security demand could threaten survival even without a long criminal trial. The law belongs in a chapter on print culture because censorship acted through the material economy of printing: presses, deposits, copies and equipment. It also reminds us that the growth of newspapers and associations was never merely a story of expanding freedom. The same infrastructure that enabled rapid political communication made editors and printers identifiable targets of regulation.

61.29 The print archive is rich precisely because it is selective

Printed sources are often easier to date and attribute than oral traditions or anonymous manuscripts, yet survival is highly unequal. Government reports and gazetteers were systematically preserved; expensive books entered libraries; newspapers and cheap pamphlets were discarded, damaged or lost. Publications with long institutional support are far more likely to survive than unsuccessful experiments. Catalogues also privilege

named authors and formal titles, whereas advertisements, handbills and subscription notices may reveal everyday print economics more directly. The historian must therefore read absence cautiously. A missing newspaper run does not prove that the paper lacked influence, while a well-preserved official report may overstate the administrative viewpoint simply because the archive retained it. Table 61.1 separates what different print sources can establish from what they cannot.

61.30 Conclusion: print multiplied publics while preserving unequal access

Colonial print transformed Mithila, Vajji and Anga by multiplying the speed, reproducibility and geographic reach of written communication. It linked local writers to metropolitan presses, schools to textbooks, associations to newspapers, and readers to postal and railway networks. Yet print did not produce one homogeneous public. English, Hindi, Urdu, Maithili and Sanskrit occupied different institutional niches; Tirhuta, Devanagari and Perso-Arabic scripts interacted with distinct technologies; and access remained structured by education, gender, class, caste, geography and capital. The early Maithili journals of the twentieth century are especially important because they show a literary language building a modern public sphere through multilingual and technologically constrained choices. The central historical shift was therefore not from silence to print, or from manuscript to modernity, but from relatively bounded textual networks to a denser field in which printed arguments could be reproduced, contested, archived and turned into regional social claims.

Table 61.1 — Evidence for colonial print culture: what each source can and cannot establish

Source / evidence	What it can establish	Main interpretive caution
Printed books and imprints	Date, printer/publisher, place of printing, editions and textual framing.	Place of printing is not necessarily the social origin of author or readership; surviving books favour durable and better-funded publications.
Newspapers and periodicals	Recurring debates, advertisements, contributors, language/script choices, association activity and changing public vocabulary.	Runs are often incomplete; circulation may be unknown; editorials do not automatically represent all readers.
Press-registration and legal records	Named printers/publishers, press locations, declared titles, securities, prosecutions and state regulation.	Records reflect what the state required or investigated and may omit informal or ephemeral circulation.
District gazetteers and postal statistics	Local press institutions, libraries, newspaper reading, postal volume and communication infrastructure.	Administrative descriptions are selective; postal counts do not identify unique readers or content.
School textbooks, grammars and dictionaries	Institutionalized spellings, categories, curricula, language hierarchies and standardizing practices.	Prescribed norms do not prove identical household speech or actual classroom use.
Association reports, petitions and letters	Organized language, regional and reform claims; named participants; circulation of arguments.	Association leadership can overrepresent educated, caste or class elites.
Surviving Maithili journals	Literary networks, bilingual/trilingual practice,	Start dates and issue runs can be inconsistent across

Source / evidence	What it can establish	Main interpretive caution
	script choice, regional discourse and authorship.	retrospective sources; survival is uneven.

Chapter 62 — Railways, Roads and Changing Markets

Railways reorganized the economic geography of Mithila, Vajji and Anga without erasing rivers, roads, ferries or animal transport. South of the Ganga, the East Indian Railway reached major Anga towns in the early 1860s; north of the river, the Tirhut network expanded from famine-relief construction in the 1870s into a branching metre-gauge system. Stations and junctions changed market hierarchy, roads increasingly became railway feeders, and new links drew frontier trade toward railheads. At the same time, flood ecology, river crossings, gauge breaks and the continuing need for carts preserved substantial friction. This chapter reconstructs that layered transport economy and treats market integration as an uneven historical process rather than an automatic result of railway mileage.

62.1 Transport change was a reordering of networks

Colonial transport history in Mithila, Vajji and Anga cannot be reduced to a sequence in which railways arrived and older routes vanished. Before rail construction, the Ganga and its tributaries, ferries, seasonal roads, carts, pack animals and foot traffic already connected village production to market towns and longer-distance commerce. Railways entered this existing geography and altered the relative cost, speed and reliability of particular routes. They encouraged some towns to become junctions or collection centres, reduced the commercial advantage of certain older road and river markets, and made feeder roads more valuable. Yet much traffic still had to reach a station by cart, cross a river by ferry, or continue toward Nepal over roads and tracks. The historical question is therefore not whether rail replaced road and river, but how several transport systems were recombined into a new hierarchy of accessibility.

62.2 Rivers remained economic infrastructure

The Ganga had long carried grain, salt, textiles, timber and passengers through Anga and the wider middle Gangetic plain. District gazetteers continued to describe river traffic even after railway expansion, because bulk goods and settlements away from the track still depended on water. Bhagalpur's official account noted both the long-standing importance of the Ganga route and the persistence of steamer traffic, even as railway competition reduced some forms of boat movement. Ferries were equally important where railway lines reached opposite banks but no bridge connected them. River transport thus survived not as a residual of a premodern economy but as one component of a multimodal system. Seasonal depth, channel migration, flood behaviour and the location of ghats shaped costs in ways that railway mileage alone cannot reveal.

62.3 Anga entered the railway era earlier than much of north Bihar

The eastern and southern part of the study region acquired major railway connections relatively early. The East Indian Railway reached Bhagalpur in the early 1860s and was extended to Monghyr in February 1862. This chronology mattered because it tied important Ganga towns to the Calcutta-oriented railway system before the Tirhut network north of the river was built. It also created uneven regional experiences of "railway modernity": places along the East Indian Railway encountered station-centred commerce, railway employment and regular train schedules decades before some flood-prone parts of northern Mithila. Such unevenness cautions against treating colonial transport as a single regional event. Different subregions entered the new network through different companies, gauges, junctions and river crossings.

62.4 Jamalpur created an industrial railway node

Jamalpur shows that railway infrastructure could create more than a transport stop. The East Indian Railway's locomotive workshops were established there in 1862, and the town's subsequent growth was closely tied to railway employment. The Monghyr gazetteer described the workshops as the district's largest industrial concern and recorded workmen's trains carrying employees from surrounding directions. Coal and other supplies moved into the district partly to serve this industrial complex. The railway therefore changed labour markets, commuting patterns and urban demand as well as freight movement. Jamalpur was not simply a place through which commodities passed: it became a production and repair centre whose wages, housing needs and supply requirements generated a new local economy. Chapter 63 returns to the labour implications of such transport-linked employment.

62.5 The Tirhut Railway began in famine and scarcity policy

North Bihar's railway chronology was closely connected with scarcity management. Construction of the Tirhut line began in 1874 as a provincial project during a period of famine relief, and the Dalsing Sarai–Samastipur–Darbhanga section opened in November 1875. The origin is historically significant because it joined two colonial objectives that were often presented together: immediate employment during distress and permanent infrastructure for the future movement of grain and people. A famine-relief railway, however, should not be interpreted as proof that transport alone could prevent famine. Access to food depended on prices, wages, purchasing power, local distribution and entitlement as well as physical carriage. The line's long-term importance came from its later incorporation into an expanding commercial network.

Figure 244 — A layered transport system: river, road, rail, ferry and frontier routes

62.6 Samastipur became a junction because networks intersected there

The opening of the Tirhut Railway gave Samastipur a new role as an operational and commercial junction. The extension to Muzaffarpur in 1877 and later branches increased the number of routes converging there. By the early twentieth century the Bengal and North-Western Railway also maintained a locomotive workshop at Samastipur employing about a thousand hands according to the Darbhanga gazetteer. Junction status concentrated railway staff, repair functions, warehousing, passenger movement and wholesale exchange. This did not mean that nearby rural markets ceased to matter. Rather, the station

became a point at which local carts and feeder routes met long-distance rail movement, allowing traders to assemble or redistribute larger consignments.

62.7 Railway expansion followed a branching rather than a single-line logic

After the first Tirhut section, new links progressively connected Muzaffarpur, Jhanjharpur, Hajipur and other points. The network's historical importance lay in branching. A main line alone could lower costs only for places near its stations; branches widened the catchment area and changed which roads functioned as feeders. Extensions in the 1880s and later connected market towns that had previously relied more heavily on river crossings or long cart journeys. The result was not uniform accessibility. Villages remained unequally distant from stations, and flood-season roads could still be impassable. Railway maps therefore need to be read together with road and hydrological evidence rather than as self-sufficient measures of economic integration.

62.8 Gauge and company boundaries shaped practical connectivity

Colonial railway systems were built under different companies and administrative arrangements, and connections were not frictionless. The Tirhut system was metre gauge, while the East Indian Railway used broad gauge. Freight or passengers moving between systems could face transshipment, ferry crossings or schedule changes. The Bengal and North-Western Railway began working the Tirhut system in 1890, creating a more integrated operating network north of the Ganga, but the river remained a major break in through movement. For economic history, “connected by railway” is therefore too simple a category. A line could exist on both sides of a river without providing wagon-through movement, and the time or cost of transfer could preserve advantages for older routes.

62.9 Ghats and ferries were railway infrastructure too

The railway age increased rather than eliminated the importance of certain ghats. At points where no railway bridge crossed the Ganga, ferries and steamers connected systems on opposite banks. The Monghyr gazetteer described the link between the Bengal and North-Western Railway at Simaria Ghat and the East Indian Railway at Mokameh Ghat, while Bhagalpur's network similarly used river crossings to connect lines north and south of the Ganga. Such arrangements created bottlenecks but also concentrated commercial activity around landing places. A transport history that counts only route miles misses these transfer spaces. Ghats were logistical nodes where wagons, boats, passengers, carts, porters and merchants interacted.

62.10 Roads were increasingly designed as railway feeders

Railway expansion did not make road construction obsolete. The Darbhanga gazetteer explicitly described road extension as a means of providing feeders to the railway. Roads radiated from Darbhanga, subdivisional headquarters and stations such as Sakri, Jhanjharpur and Nirmali toward markets and the Nepal frontier. This feeder logic altered the purpose of road spending: a road could become valuable because it shortened the cart journey to a station rather than because it carried traffic for the entire interregional route. In higher and better-drained country, roads could support year-round traffic; in low-lying tracts, seasonal inundation sharply reduced reliability. The railway thus created new incentives for road investment while exposing old inequalities in terrain and drainage.

62.11 Flood-prone Mithila made all-weather roads expensive

The central and south-eastern portions of Darbhanga district were described as poorly served by good communications because annual flooding made embankment, bridging and drainage expensive. Roads that appeared on official maps could be difficult or impossible to use during the rains. Some projects required substantial private or landed support: the Darbhanga–Jaynagar road, for example, was bridged throughout at the expense of the Darbhanga Raj. This contrast between mapped mileage and seasonal usability is crucial. Market access depended not simply on whether a road existed but on surface, elevation, bridge provision, maintenance and flood conditions. Railway embankments could offer a more dependable trunk route while leaving last-mile access vulnerable.

Figure 245 — Selected transport milestones in Mithila–Vajji–Anga, c.1860–1907

62.12 Bullock carts remained the indispensable last mile

District accounts continued to describe bullock carts as common conveyances for goods and passengers. Their persistence explains how railways could expand without directly reaching most villages. Grain, oilseeds, tobacco, hides and other commodities were collected from rural production zones and carried to stations or larger markets by cart; imported salt, kerosene, cloth and other goods moved outward in the reverse direction. Cartage costs therefore remained part of railway-era prices. The economic radius of a station depended on how far traders could profitably move goods over local roads. Where roads were poor or flooded, the effective railway catchment narrowed. Railway and cart transport were complements as often as competitors.

62.13 Sakri–Jaynagar linked rail expansion to the Nepal frontier

The Sakri–Jaynagar line, opened in 1905, is a particularly clear example of transport reaching toward the India–Nepal borderland. The Darbhanga gazetteer noted that much of its earthwork had been completed during famine-relief operations in 1897 and that the line opened a tract previously remote from railway access. Passing through Madhubani and toward Jaynagar, it tapped grain supplies moving from Nepal and connected frontier trade more directly with the railway network. Yet the border itself was not converted into a rail-only corridor. Goods from Nepal still reached railheads by carts, pack bullocks, coolies and local roads. The line shortened one segment of the journey while leaving the cross-border economy multimodal.

62.14 Nepal trade reveals the limits of railway determinism

Darbhanga's official trade description stated that most commerce with neighbouring Indian districts had become rail-borne, while trade with Nepal continued to use carts, pack animals and human carriers. Grain, oilseeds and timber moved southward; piece-goods, salt and kerosene moved toward Nepal. This mixed system is analytically valuable because it shows how railway influence could extend beyond the track. A frontier trader might still use animal transport for the mountain or Tarai segment but choose a railway-linked town as the wholesale destination. Rail access therefore reshaped prices and market orientation without physically penetrating every part of the route. Transport technologies operated in sequence rather than in isolation.

62.15 Market towns gained or lost relative position

New transport routes changed the hierarchy among markets. The Darbhanga gazetteer observed that Rusera, once the largest market in the southern part of the district, had lost much of its importance after the opening of the railway, although it remained flourishing. This wording is important: decline was relative, not disappearance. Markets situated favourably near stations, junctions or feeder-road intersections could attract wholesale activity, while older centres might lose part of their hinterland. The result was a redistribution of commercial centrality. Similar processes affected road markets where a parallel railway diverted through traffic. The railway did not “create markets” from nothing; it altered the geography within which existing markets competed.

62.16 Darbhanga, Madhubani and Samastipur became stronger collection centres

By the early twentieth century Darbhanga, Madhubani and Samastipur were identified among the principal trade centres of the district. Their importance rested on a combination of population, administrative functions, roads and railway links. Stations enabled merchants to assemble consignments for export and to receive imported goods in larger volumes. Madhubani's growing connection to the Sakri–Jaynagar corridor also strengthened its relation to northern and Nepal-bound trade. Samastipur's junction and workshop functions added an industrial dimension. These examples show why transport history must be written at the scale of nodes as well as lines: a route becomes economically consequential through the places where goods are stored, financed, weighed, transferred and sold.

62.17 Commodity geography became more tightly linked to transport geography

The Darbhanga gazetteer listed exports such as rice, gram, pulses, linseed, mustard seed, tobacco, hides and ghee, and imports including salt, kerosene, coal, gunny bags and European cotton goods. In Monghyr, coal traffic was connected to the Jamalpur workshops, while agricultural produce moved through railway market towns such as Barhiya, Lakhisarai and Sheikhpura. Railways did not determine what a region produced, but they changed the feasible distance over which bulky or time-sensitive goods could be marketed. Commodity flows therefore need to be reconstructed alongside station location, freight handling and road access. A single district could simultaneously export and import grain depending on season, quality and market conditions.

62.18 Railway stations became commercial institutions

A station was more than a platform. It concentrated booking, weighing, loading, storage, cart stands, labour and information about prices and destinations. Traders adjusted procurement to train schedules and

freight rates; nearby land could acquire new commercial value; shops and lodging clustered around passenger movement. Official gazetteers often name stations when describing markets precisely because station access had become part of a town's economic identity. At the same time, station-centred evidence can exaggerate railway influence by making recorded traffic more visible than informal local exchange. The historian should distinguish what passed through official freight accounts from what continued to move through weekly markets, village credit networks and unrecorded cart traffic.

62.19 Railways intensified urban and industrial labour demand

Transport infrastructure generated employment directly through construction, track maintenance, stations, workshops and clerical services. Jamalpur and Samastipur demonstrate the scale such employment could reach. Railway labour also produced secondary demand for food, housing, fuel, repair services and retailing. Workmen's trains at Jamalpur show that labour catchments could extend beyond walking distance and that commuting itself became part of the transport economy. These effects complicate any account focused only on freight. A railway line changed local labour markets even when the surrounding countryside remained overwhelmingly agrarian. The next chapter will examine migration and mobility more fully, but transport-linked employment already reveals how infrastructure reorganized household strategies.

62.20 Fairs and pilgrimage traffic adapted to stations and roads

The regions' fairs, sacred centres and periodic markets predated the railway, yet improved transport changed the scale and timing of attendance. Stations and feeder roads could make pilgrimage sites accessible to visitors from a wider radius, while carts and ferries still handled the final segment where no rail connection existed. Passenger traffic brought vendors, lodging providers and carriers into the same seasonal economy. The effect was not a simple commercialization of religion; fairs had long combined ritual and exchange. Railways altered the spatial reach of those exchanges and could concentrate activity around particular arrival points. This continuity with Chapter 51 is important: colonial transport transformed public culture partly by changing how people reached already established places of congregation.

Figure 246 — How railway access could reorder market hierarchy

62.21 Famine relief and market integration were related but not identical

Colonial officials often justified transport investment by arguing that railways and roads could move grain into scarcity areas. The Tirhut Railway's famine-relief origins and the Sakri–Jaynagar earthworks illustrate that connection directly. Better transport could reduce the physical isolation of a deficit locality and allow supplies to move more rapidly. But famine was never only a transport problem. If wages collapsed or food prices rose beyond household purchasing power, grain could be present in a connected market while vulnerable people still starved. Transport therefore altered one constraint within a larger political economy of entitlement, relief, prices and employment. This distinction preserves the lessons of Chapter 58 while explaining why colonial administrations nevertheless treated communications as a central anti-famine instrument.

62.22 Price convergence offers one measure of market integration

Economic historians have used district price series to test whether railway expansion reduced price differences across space. John Hurd's classic study linked the growth of the network to expanding markets, while later work by Tahir Andrabi and Michael Kuehlwein found that railways contributed to price convergence but did not account for the whole decline in dispersion. Their result is useful for this region because it resists a technological monocause. Mithila, Vajji and Anga already possessed riverine, road and merchant networks before railway construction. Railways lowered some transport costs and increased speed, but pre-existing trade, harvest conditions, information flows, storage and local institutions also influenced prices. Market integration was cumulative and uneven rather than born at the moment a station opened.

62.23 National estimates should not be projected mechanically onto the region

Recent quantitative studies of colonial Indian railways estimate substantial aggregate effects on trade, welfare or long-run growth. Such findings establish that railways mattered at the scale of British India, but they do not replace regional reconstruction. A national average cannot tell us whether a flooded road near Jhanjharpur was usable, whether a merchant at Jaynagar relied on pack transport from Nepal, or whether an older market lost trade to a nearby station. The regional evidence shows multiple mechanisms operating simultaneously: lower trunk transport costs, new junctions, feeder-road investment, industrial employment and changes in market hierarchy. Quantitative national research is most useful here as a framework to test against local primary sources, not as a substitute for them.

62.24 River crossings remained costly points of friction

Before major bridges, crossing the Ganga often required unloading, ferrying and reloading passengers or goods. Where different gauges or companies met, transfer could add further delay. These frictions explain why railway maps can overstate effective integration. A straight line on a map may conceal hours of waiting at a ghat, seasonal uncertainty, handling charges or damage to cargo. Conversely, a well-organized steamer connection could make a seemingly discontinuous route commercially viable. The economic importance of Mokameh–Simaria and other ferry connections lay precisely in their capacity to link otherwise separate railway systems. Transport cost must therefore be understood as a chain of operations rather than the mileage of a single mode.

62.25 Roads parallel to railways could lose through traffic

The Monghyr gazetteer recorded that the Tirhut road running through important markets such as Lakhminia, Ballia, Begusarai and Teghra had lost much of its importance because the railway ran parallel to

it. This is the road equivalent of Rusera's relative loss of market centrality. When rail offered cheaper or faster long-distance carriage, a road could shift from trunk-route status to local or feeder use. Such changes affected inns, cart operators, roadside markets and settlements that had depended on through traffic. Yet the road still mattered for access between stations and villages. Railway competition therefore changed road function more often than it eliminated roads outright.

62.26 Infrastructure could reorganize land values and settlement

Stations, workshops, bridges and improved roads created new focal points for shops, storage and housing. Although district gazetteers do not provide a complete series of land values around every station, the concentration of trade and employment at junctions implies a redistribution of locational advantage. A plot near a station or feeder-road intersection could acquire commercial uses unavailable to equally fertile land farther from transport. Conversely, settlements bypassed by a new line might lose part of their service economy. These processes were gradual and conditioned by ownership, municipal institutions and flood risk. The important point is that transport infrastructure changed the economic meaning of location within the same agrarian landscape.

62.27 Railway embankments also became hydrological structures

In floodplains, a raised railway or road embankment was not environmentally neutral. The Monghyr gazetteer's discussion of the 1904 floods noted how the railway and the Tirhut road could obstruct or pond floodwater even while the railway itself remained intact. Bridges, culverts and drainage openings therefore mattered as much as the embankment's height. Similar engineering dilemmas were inherent in low-lying Mithila, where communications had to cross shifting channels and seasonal inundation. Infrastructure could improve market access in ordinary conditions while altering the path or duration of floodwater during exceptional events. This dual role links transport history directly to the ecological history developed earlier in the volume.

Figure 247 — Transport infrastructure and flood ecology

62.28 Infrastructure produced winners and losers

Transport investment distributed benefits unevenly. Merchants near new stations, railway employees, cart operators on feeder routes and consumers of imported goods could gain from lower costs or new demand. Older road markets, ferry points bypassed by new alignments, and service providers tied to former routes could lose traffic. Landholders could benefit from better access to commercial crops, but the same integration might expose cultivators to wider price fluctuations or strengthen creditor control over marketed surplus. No single social group experienced the railway in one way. The distributional question is essential because aggregate increases in trade do not tell us who captured the gains from reduced transport costs.

62.29 The official archive measures infrastructure better than everyday mobility

Railway administration reports, district gazetteers and District Board accounts are unusually good at recording route miles, opening dates, stations, bridges and major market centres. They are less complete for informal paths, seasonal detours, small ferries, women's local travel, unpaid carrying work and the daily decisions by which households reached a market. Freight returns reveal recorded consignments but not necessarily village exchange or smuggling across a border. Official sources also tend to describe infrastructure from the perspective of administrative utility and revenue. A careful reconstruction therefore combines engineering and railway records with trade descriptions, price series, maps and local evidence, while treating each source as a partial view of movement.

62.30 Conclusion: faster connections created a new but uneven market geography

By the early twentieth century, Mithila, Vajji and Anga had been drawn into a denser transport system in which railway lines connected major towns and junctions, roads increasingly acted as feeders, ferries linked networks across the Ganga, and carts or pack transport still carried the last or frontier segment. The result was substantial market reorientation: Samastipur and Jamalpur gained transport-linked functions, Madhubani and Jaynagar became more closely tied to rail-mediated trade, and some older markets or roads lost relative importance. Yet the region remained shaped by flood ecology, river crossings, gauge changes and unequal all-weather access. Colonial transport accelerated exchange without homogenizing space. It also made movement of labour easier, setting up the next chapter's examination of migration, seasonal work and longer-distance mobility.

Table 62.1 — Evidence for transport and market change: strengths and limits

Source / evidence	What it can establish	Main interpretive caution
Railway administration reports and opening records	Line ownership, gauge, station and section opening dates, working arrangements and route mileage.	Administrative dates establish formal operation, not the intensity or social distribution of use.
District gazetteer communication chapters	Roads, stations, ferries, markets, local traffic, flood constraints and official assessments of accessibility.	Descriptions privilege administratively visible routes and may understate informal paths and seasonal mobility.
Trade and station freight returns	Recorded commodities, tonnage, origins/destinations and growth of rail-borne traffic.	Official freight omits informal exchange and may not reveal who captured commercial gains.
District Board road accounts	Road mileage, metalling, bridges, maintenance and	Mapped mileage is not equivalent to all-weather

Source / evidence	What it can establish	Main interpretive caution
	feeder-road priorities.	usability, especially in flood-prone tracts.
Market and fair descriptions	Relative importance of towns, periodic markets, commodity specialisation and changes after new links.	Qualitative terms such as flourishing or declining do not provide a complete price or turnover series.
Price series	Spatial convergence or divergence and response to harvest or transport shocks.	Prices reflect storage, information, harvests and institutions as well as transport costs.
Maps, flood reports and engineering evidence	Alignment, ghats, embankments, bridges, drainage openings and relationships to floodplains.	A mapped line cannot by itself show seasonal passability or local hydrological consequences.
Local histories and oral evidence	Remembered routes, station neighbourhoods, occupations, market shifts and everyday travel practices.	Retrospective memory requires dating control and comparison with contemporary records.

Chapter 63 — Labour Migration

Labour migration became one of the most consequential connections between the agrarian households of Mithila, Vajji and Anga and the expanding colonial economy. Yet there was no single migrant stream. Seasonal workers, circular urban migrants, railway and workshop labourers, plantation recruits, women moving within family labour strategies, and indentured emigrants faced different destinations and different degrees of freedom. Railways lowered travel frictions, but recruitment networks and labour law often determined whether movement remained reversible. This chapter reconstructs those differentiated circuits while keeping census categories, household strategies and coercive labour regimes analytically distinct.

63.1 Labour migration was several mobilities, not one exodus

Colonial labour migration from Mithila, Vajji and Anga took several forms that must be kept analytically separate. Some cultivators and labourers left for a few weeks or months during slack agricultural seasons; others worked repeatedly in Calcutta, Howrah or railway centres while maintaining a village household; some moved with families to plantation zones; and a much smaller share entered overseas indenture. Census tables tend to flatten these movements because they record birthplace or residence at a particular date, not the full sequence of departure, return and repetition. A history of labour migration therefore has to reconstruct circuits rather than assume that every person enumerated outside a home district had permanently left it. The key question is not simply how many moved, but what kind of labour relation, distance, recruitment mechanism and probability of return defined each movement.

63.2 Agrarian pressure made mobility a household strategy

The agrarian economy created recurring incentives to seek cash earnings outside the village. Small holdings, unequal access to land, rent demands, indebtedness, crop failure and limited local non-farm employment could make wage work elsewhere attractive even when a household remained committed to cultivation. Migration did not necessarily express rejection of agriculture; it could help sustain it. Earnings from outside work could meet rent or debt obligations, finance marriages and rituals, purchase grain, replace lost cattle, or support cultivation during a difficult season. Anand A. Yang's study of Bihar migration usefully emphasizes the decision-making of rural households rather than depicting peasants as mechanically expelled from the countryside. For the present region, this perspective is especially important because recurrent flood and rainfall risk combined with dense agrarian settlement to make income diversification rational even where land remained socially central.

63.3 Flood, scarcity and the agricultural calendar shaped departure

Seasonality mattered. Flood-prone parts of north Bihar could lose crops or local employment during destructive inundation, while a failed monsoon or poor harvest reduced the demand for agricultural labour and household food stocks. Conversely, peak sowing, transplanting and harvesting seasons increased the value of returning home. This rhythm made temporary migration compatible with cultivation: departure could occur when village labour demand was low and return when family fields or local employers required workers. The railway network described in Chapter 62 reduced travel time but did not erase the agricultural calendar. Instead it could make repeated movement more feasible. Because district-level sources are better at recording catastrophic scarcity than ordinary annual circulation, routine seasonal migration is probably less visible in the archive than famine- or crisis-linked movement.

63.4 Land, debt and social hierarchy shaped who could migrate

Migration was not equally available or equally necessary to all. Households with little or insecure land were more exposed to wage fluctuations and food shortfalls, yet the poorest could also lack the money, contacts or physical security needed for a long journey. Better-connected cultivators might finance a temporary move and use earnings to strengthen a rural position. Caste and community networks could influence access to recruiters, lodging, credit and jobs, but they should not be treated as timeless occupational destinies. The same network could facilitate mobility in one generation and constrain it in another. Colonial observers often described labour supply through caste stereotypes; a social history must instead ask how property, debt, household composition, local wages, transport access and interpersonal connections interacted in particular places.

63.5 Long-distance wage mobility predated the railway

Railways accelerated labour migration, but they did not create it from nothing. River transport, roads, pilgrim routes, military service, artisanal travel and seasonal agricultural work had long moved people through the Gangetic world. Early colonial recruitment for indigo, public works and urban service also used pre-rail networks. The nineteenth-century transformation lay in scale, speed and regularity: steam navigation and railways connected recruiting districts to metropolitan and plantation labour markets more predictably, while employers developed specialised intermediaries to mobilise labour. Treating the railway as a single causal break would therefore repeat the same technological determinism rejected in Chapter 62. The more defensible claim is that new transport infrastructure widened the radius within which older practices of temporary mobility could be reorganised.

Figure 248 — Major labour-migration circuits from Mithila, Vajji and Anga

63.6 Railways lowered the friction of repeated movement

By the late nineteenth and early twentieth centuries, railways made some labour circuits cheaper, faster and more repeatable. A worker from Tirhut or Anga could reach major junctions, Calcutta-oriented lines or feeder routes with less dependence on long foot marches and river stages. Research on railways and migration in colonial India shows that transport expansion interacted with pre-existing labour demand and migration networks rather than operating in isolation. This matters for interpretation: a line opening did not

automatically produce migration from every village it touched, but once a destination had jobs and migrant contacts, the railway could strengthen chain migration and shorten return cycles. Stations consequently became social as well as commercial nodes—places where recruiters, experienced migrants, first-time travellers and news about wages converged.

63.7 Calcutta–Howrah was the largest metropolitan pole to the east

Calcutta and Howrah drew labour from a wide hinterland that included Bihar. The metropolis concentrated docks, construction, transport services, municipal work, workshops, domestic service and factory employment, while the adjoining industrial belt contained large jute mills and engineering establishments. Census accounts of Calcutta repeatedly noted the importance of migrants from Bihar and the United Provinces. For the study region, Muzaffarpur and other north-Bihar districts formed part of this wider supply zone, though the intensity of migration varied sharply by district and community. The metropolis should therefore be treated as a destination system rather than a single occupation: migrants might move between casual carrying, dock work, mill labour, services and construction according to contacts and demand.

63.8 Jute and factory labour depended on migrant supply

Industrial eastern India relied heavily on workers who were not born in the mill towns where they worked. Studies of factory labour supply show the importance of migrants from Bihar, the United Provinces, Chota Nagpur and Orissa in the making of the eastern industrial workforce. Recruitment did not usually operate through an impersonal labour exchange. Jobbers, sardars, foremen and experienced workers connected village origins to particular mills or departments. This helped employers obtain labour but also gave intermediaries influence over hiring, advances, discipline and accommodation. A migrant's employment prospects could therefore depend as much on a social connection as on the published wage. The resulting labour force remained mobile: workers could change employers, return home seasonally or follow a jobber elsewhere.

63.9 Urban labour included much more than factory work

Factory employment is disproportionately visible because mills generated records, commissions and labour histories. Yet a large share of migrant labour was casual or service work: portering, carting, railway loading, dock labour, building, municipal work, hawking, domestic service and small workshops. These occupations often had fluctuating demand and weak documentation. They also allowed migrants to combine jobs or enter the city without immediately joining a formal factory. This breadth helps explain why birthplace statistics cannot be translated directly into an industrial workforce. Metropolitan migration was a labour ecology in which workers shifted among tasks, employers and neighbourhoods, and where earnings depended on daily hiring, contacts and physical health as much as on a stable contract.

63.10 Jobbers and sardars converted social networks into labour-market institutions

Labour contractors and intermediaries were central to colonial migration. Tirthankar Roy's comparative work on sardars, jobbers and kanganies shows that employers repeatedly relied on brokers who could recruit, supervise and retain workers using relationships that the firm itself did not possess. In eastern India, the jobber or sardar might draw on village, kin or caste ties, provide an advance or information, and then exercise influence at the workplace. Such intermediation reduced employers' search costs but could create

dependency, deductions and favouritism. It also gave workers a channel through which to bargain or move collectively. Social networks were therefore neither purely protective nor purely coercive; they were labour-market institutions whose effects depended on the power of the intermediary and the worker's ability to exit.

63.11 Circular migrants often remained members of rural households

Many migrants did not establish an independent urban household. They retained claims, obligations and identities in the village, sent money or goods home, and returned for agricultural work, festivals, marriage negotiations or illness. This two-ended life explains why contemporary observers sometimes misread recurrent absence as instability or 'absenteeism'. From the household's perspective, repeated movement could be a deliberate allocation of labour across places. The city provided cash; the village provided land access, family care, food security and a place of return. Circularity also meant that urban labour markets could expand without equivalent permanent urbanisation. This pattern has deep historical significance for Bihar because later twentieth-century migration continued to rely on similar multi-local household arrangements, even though destinations changed.

63.12 Village connections lowered risk for new migrants

A first journey was risky because wages, lodging, employers and routes were uncertain. Earlier migrants could reduce that uncertainty by arranging a job, sharing a room, advancing travel money or explaining how to navigate stations and contractors. Once such links formed, migration could become self-reinforcing: one worker's departure created information for relatives and neighbours, and a destination acquired a recognisable origin cluster. Colonial sources sometimes described these clusters as evidence of caste preference, but chain migration offers a more dynamic explanation. Networks emerged through previous movement and could cross caste boundaries where employers or recruiters found it useful. They should be reconstructed historically rather than treated as fixed cultural traits.

Figure 249 — Circular migration as a household economic cycle

63.13 Remittances transferred urban earnings into the agrarian economy

The economic meaning of migration cannot be measured only at the destination. Money and goods sent or carried home could pay rents and debts, smooth consumption after a crop loss, finance ceremonies,

purchase livestock or tools, and alter bargaining within the household. Formal postal remittance data capture only part of this flow because migrants also carried cash personally or entrusted it to acquaintances. Remittances could reduce vulnerability, but they also exposed families to irregular payment, theft, illness or sudden unemployment at the destination. A household that depended on a migrant wage therefore linked its welfare to distant labour-market conditions. Migration diversified income while simultaneously widening the geography of risk.

63.14 Absence redistributed work inside the household

When an adult man left seasonally, the labour he had performed did not disappear. Women, older people, children, hired workers or relatives might take on cultivation, livestock care, marketing and negotiations with landlords or creditors. In some households migration could strengthen women's day-to-day responsibility without necessarily increasing their formal control over property or migration decisions. The social cost of mobility was therefore partly borne by those who stayed. This is one reason to treat migration as a household process rather than an individual wage choice. The destination wage depended on unpaid and under-recorded work at the origin that maintained land, children and social obligations until the migrant returned.

63.15 Women's migration cannot be read from birthplace data alone

Colonial censuses recorded very high levels of female movement associated with marriage, so a woman enumerated outside her district of birth cannot automatically be classified as a labour migrant. At the same time, women did migrate for work, especially where employers recruited families or demanded female labour. Samita Sen has shown how debates over women's migration exposed conflicts among patriarchal household claims, recruiters, planters and the colonial state. For this region, a particularly revealing contemporary distinction treated migration from Darbhanga to Bhagalpur as relatively permanent because wives also moved. The example demonstrates both the importance of women's movement and the danger of using sex ratios or birthplace tables without understanding the social form of migration.

63.16 Assam tea created a distinct long-distance labour regime

Assam's tea industry expanded through imported migrant labour recruited from outside the province. Jayeeta Sharma and Rana P. Behal both emphasize that the plantation workforce was not simply a local labour market: migrant workers were recruited on contracts into an industry dominated by European planters and oriented toward export. The distance of the gardens from recruiting districts, the cost of transport and employers' desire to retain workers encouraged forms of labour control much stronger than those typical of casual urban employment. For migrants from Bihar and neighbouring regions, Assam therefore represented a qualitatively different circuit from seasonal work in Calcutta or nearby districts. Movement to the tea garden could involve a household relocation and a far higher barrier to return.

63.17 Professional recruiters and sardars competed to control plantation recruitment

Plantation recruitment passed through changing systems of contractors, *arkatis* and *sardars*. Abuses by professional recruiters produced repeated official enquiries and attempts at regulation. Planters and officials later promoted *sardari* recruitment as an alternative that supposedly relied on kin, village and community trust. Samita Sen's work shows that this contrast was partly ideological: *sardars* were presented as non-market intermediaries even though they also served plantation labour demand and could wield substantial power. The important historical point is not to label one system 'free' and the other 'coercive', but to examine who

supplied information, advances and transport, how consent was obtained, and whether the worker could realistically reverse the decision.

63.18 Tea plantations recruited families because women's labour mattered

A distinctive feature of Assam plantation migration was the importance of family recruitment. Tea cultivation required female as well as male labour, and planters had an interest in a settled workforce that could reproduce itself. This made women's recruitment economically significant and politically controversial. Family migration could give women paid work unavailable in many origin villages, but it also placed them within a tightly controlled plantation settlement. The presence of wives and children increased the probability that migration would become long-term or permanent, while also making the costs of desertion or return more complex. Plantation demography must therefore be understood through the combined history of labour demand, household formation and gender regulation.

63.19 The Assam system combined contract with coercive enforcement

The Assam labour regime was sustained by special legislation and by workplace practices that sharply constrained exit. Behal and Prabhu Mohapatra describe an indenture system in which economic and physical coercion were integral to plantation labour control, while the colonial state repeatedly accommodated planter interests. The 1906 Assam Labour Enquiry Committee documented recruitment practices, transport, conditions and worker complaints in unusually detailed form. Such records make Assam migration highly visible compared with ordinary seasonal labour, but that visibility should not be mistaken for representativeness. It reflects the fact that the state treated plantation labour as a special regulatory problem. The appropriate comparison is therefore one of labour regimes, not simply migrant numbers.

63.20 Regulation of women's recruitment exposed competing claims to consent

The Assam Labour and Emigration Act VI of 1901 re-established a tighter regulatory framework and placed special constraints on women's recruitment. The legal debate did not simply protect autonomous female choice. As Sen demonstrates, the state often deferred to household and marital claims, treating a husband's or family's authority as relevant to whether a woman could migrate. Thus a measure presented as protection could also restrict women's capacity to decide independently. The episode is central to labour history because it shows that colonial definitions of 'free migration' were gendered. Freedom of contract for employers, patriarchal authority in the household and women's own labour choices did not coincide.

Figure 250 — Labour mobility along a spectrum of control

63.21 Proximity made the Dooars different from distant Assam

Plantation labour markets were not identical. Evidence collected in the Assam labour enquiries noted that some workers regarded the Dooars as more attractive because return was easier. This comparative preference reveals how distance and exit shaped labour choice. A worker might accept plantation wages while avoiding the stronger isolation associated with far eastern Assam. Transport improvements could therefore alter not only the volume of migration but the relative attractiveness of destinations. Where a migrant could return at will, household circularity remained possible; where travel, contract and employer control raised the cost of exit, migration more readily became a form of labour settlement.

63.22 Overseas indenture formed a separate and uneven stream

Bihar contributed labour to the nineteenth-century overseas indenture system that supplied Mauritius, British Guiana, Trinidad, Fiji and other colonies after the abolition of slavery. Yet participation was highly uneven across districts, and the study region should not be treated as if every locality supplied migrants at the same rate as the best-known recruiting zones of western Bihar and eastern Uttar Pradesh. Muzaffarpur and Darbhanga do appear in studies of overseas recruitment, but the evidence requires district- and period-specific checking. Overseas indenture is therefore included here as one edge of the migration system rather than as the dominant form of labour mobility in Mithila, Vajji and Anga. Its importance lies also in the recruiting institutions and Calcutta depots that connected inland Bihar to an imperial labour market.

63.23 Calcutta could be destination, transit point and recruiting gateway

The same transport corridor could serve several kinds of migrant. Calcutta was a workplace for industrial and casual labour, but it was also a port and administrative centre through which migrants could be processed for more distant destinations. This layered role complicates simple origin-destination maps. A person counted in Calcutta might be a settled resident, a temporary worker, a railway-connected traveller or someone awaiting onward recruitment. The city consequently linked internal and overseas labour markets. That connection also allowed recruiting practices, rumours and political criticism to circulate back into Bihar through returning workers, newspapers, reform associations and official enquiries.

63.24 Anga contained important receiving as well as sending labour centres

Labour migration was not only outward from the study region. Jamalpur's railway workshops, Bhagalpur's urban economy and other transport or administrative centres drew workers from surrounding countryside and from farther away. Chapter 62 showed how the railway created concentrated employment at Jamalpur; this chapter adds the labour-market implication. Industrial and railway nodes could convert a district into both a source and a destination of migrants. Such two-way movement is obscured when Bihar is narrated only as a region of out-migration. Anga's urban and railway centres demonstrate that labour mobility reorganised population within the region as well as linking it to Calcutta and Assam.

63.25 Inter-district migration linked Mithila, Vajji and Anga

Movement between neighbouring districts could be as socially significant as migration to a distant metropolis. Census and administrative discussions record flows across district boundaries created by marriage, cultivation, service and wage labour. The Darbhanga–Bhagalpur example discussed by Sen is especially useful because officials inferred a more permanent form of movement where wives accompanied men. Inter-district migration could follow river routes, railway connections, estates and labour demand without producing the documentary trail associated with plantations. It should therefore be considered part of the same regional labour history, while keeping labour migration distinct from marriage and ordinary residential mobility wherever the sources permit.

63.26 The Nepal–Tirhut borderland sustained mobility that censuses could misclassify

The India–Nepal frontier did not function as a sealed national border in the colonial period. Markets, pilgrimage, kinship, cultivation, livestock movement and seasonal labour crossed the Tarai and north-Bihar boundary. Because political jurisdictions and census procedures differed, short-distance cross-border movement can appear statistically less visible than migration to Calcutta or Assam. The borderland also offered alternative labour and land opportunities that did not necessarily require a formal recruiter. For the history of Mithila, this mobility should be treated as part of a connected regional economy rather than as an anomalous 'international' movement projected backward from later nation-state categories.

63.27 Colonial censuses measured migration imperfectly

Census migration tables are indispensable but conceptually limited. Birthplace, current residence and administrative district do not reveal why a person moved, how long the move lasted, whether the person had already returned several times, or whether the move was for marriage, service, cultivation or wage labour. District boundaries could also change, creating apparent movement without a comparable social journey. The most mobile seasonal workers might be missed depending on census timing. For this reason, census totals should be triangulated with district gazetteers, railway evidence, labour enquiries, factory records and qualitative accounts. The objective is not to discard enumeration, but to avoid turning an administrative snapshot into a complete biography of movement.

Figure 251 — Source triangulation for colonial labour migration

63.28 Community networks mattered without determining migration destinies

Employers and colonial ethnographers frequently described particular communities as naturally suited to certain kinds of labour. Such language could harden fluid recruitment patterns into stereotypes. A more historical approach sees community concentration at a workplace as potentially produced by chain migration: once an employer trusted a sardar or a group had established lodging and contacts, subsequent recruitment from the same locality became cheaper. This process could look like a fixed ethnic or caste preference even though it arose from institutional path dependence. The lesson parallels Chapter 59: administrative and employer categories are evidence about classification practices, not timeless descriptions of social capacity.

63.29 Migration circulated language, songs, politics and experience

Workers did not carry only labour power. Return migrants brought stories about wages, cities, employers, railways, political agitation and distant social worlds. Separation, hardship and longing entered vernacular song traditions; urban residence could expose migrants to newspapers, unions, religious associations and nationalist politics. These cultural effects are difficult to quantify but essential to the socio-cultural history of migration. A village with repeated migrants could become connected to Calcutta or Assam through correspondence, remittances, recruitment chains and shared memory even when most residents never travelled. Labour migration therefore altered the information geography of Mithila, Vajji and Anga as well as their household economies.

63.30 Conclusion: colonial mobility was an unequal system of household adaptation and labour control

Colonial labour migration from Mithila, Vajji and Anga cannot be reduced either to helpless displacement or to unrestricted market choice. Rural households used mobility to diversify income, preserve cultivation and respond to seasonal or ecological risk. Railways and recruiters expanded the range of possible destinations. Yet the power to move and the power to return were unequally distributed. Urban jobbers mediated hiring; plantation contracts and special law constrained exit; women's mobility was shaped by both

labour demand and patriarchal regulation; and overseas indenture carried migrants into a still more distant contractual world. The most accurate synthesis is therefore one of differentiated mobility: agency operated within structures of land inequality, household obligation, transport cost, recruitment intermediation and colonial labour discipline.

Table 63.1 — Evidence for colonial labour migration: strengths and limits

Source / evidence	What it can establish	Main interpretive caution
Census birthplace / residence tables	District-to-district and province-to-province stocks at a census date; sex composition; broad spatial patterns	Do not reveal labour motive, duration or repeated seasonal movement; marriage migration is especially important for women
District gazetteers and settlement reports	Local observations on occupations, communications, scarcity, recruiting districts and movement	Official and uneven; often describe conspicuous migration better than routine circulation
Assam Labour Enquiry and emigration records	Recruitment channels, contracts, transport, abuses, regulation and plantation labour conditions	Over-represent regulated plantation migration relative to ordinary wage mobility
Factory, railway and municipal records	Workforce demand, workshops, occupations, wages, hiring institutions and labour intermediaries	Usually weak on origin households, remittances and return journeys
Postal / remittance evidence	Movement of cash and communication between migrants and households	Formal channels capture only part of the transfers; hand-carried cash is invisible
Newspapers, petitions and association records	Public controversies over recruitment, labour rights, women's migration and colonial regulation	Elite and literate voices are disproportionately preserved
Songs, letters, memoirs and oral traditions	Separation, aspiration, exploitation, return, gendered experience and migrant memory	Dating, authorship and representativeness require careful source criticism
Destination-side district and industrial histories	Reception, neighbourhoods, labour-market clustering and chain migration	Can obscure the agrarian and household logic that produced departure

Chapter 64 — Women and Colonial Modernity

Colonial modernity altered women's lives in Mithila, Vajji and Anga through schools, law, print, medicine, labour markets, migration and nationalist politics, but the changes were profoundly unequal. Female literacy remained low even as girls' education became an explicit field of policy; statutes changed the legal treatment of widow remarriage, consent and child marriage without ensuring uniform social compliance; hospitals and trained female personnel expanded without displacing household medicine; and political mobilisation made women publicly visible while leaving the economic weight of unpaid labour poorly recorded. This chapter reconstructs those layered transformations while treating the silences of the colonial archive as part of the history itself.

64.1 Colonial modernity was uneven, layered and contested

Women in Mithila, Vajji and Anga encountered colonial modernity not as a single transition from an old social order to a new one, but through overlapping institutions that moved at different speeds. Schools could expand while female literacy remained very low; statutes could alter legal possibilities while marriage practice changed slowly; hospitals and lady doctors could appear without displacing household medicine or dais; and nationalist mobilisation could draw women into public action without dissolving domestic obligations. The concept of modernity is therefore useful only when broken into specific processes—education, print, law, medicine, labour markets, transport, associational life and political participation. Each process was filtered through locality, class, caste, religious community, household wealth and age. The history is consequently one of selective access and negotiated change rather than a uniform story of either emancipation or decline.

64.2 The archive itself produces a gendered field of visibility

Colonial records describe women most clearly when the state had an administrative reason to count or regulate them. Census tables record literacy, marital status and some occupations; education reports count pupils and schools; medical reports count patients and trained personnel; courts preserve disputes; labour enquiries become detailed when recruitment or coercion drew official concern. Yet unpaid agricultural work, household production, child care, food processing, informal credit, ritual knowledge and oral teaching often remain faintly recorded. This imbalance matters because a literal reading of official statistics can make economically active women appear 'dependent' and culturally productive women appear absent. The chapter therefore treats archival silence as a problem of source formation. Administrative evidence is indispensable, but it must be read alongside district observation, law, print, labour history, family practice and the indirect traces preserved in oral and material culture.

64.3 Household labour was an economic institution, not a private residue

The household was one of the principal sites through which the regional economy reproduced itself. Women processed grain, prepared food, managed fuel and water, cared for children and the sick, stored seed and household goods, maintained clothing, participated in livestock care and, in many social groups, worked directly in cultivation or post-harvest activity. Such work could be essential to the viability of small farms even when it generated no separately recorded wage. Colonial economic categories tended to privilege market employment and taxable production, thereby understating the labour required to maintain workers, migrants and cultivators. The expansion of railways, cash crops and wage migration did not make this household economy disappear. On the contrary, when men migrated or spent longer periods away, the

allocation of farm supervision, care and consumption management within the household could become still more important.

64.4 Women's agrarian work varied sharply by class, caste and locality

There was no single female agrarian role across the alluvial plains, flood-prone tracts, towns and eastern districts. Elite or prosperous households could treat seclusion from field labour as a marker of status, while poorer cultivators and labouring households could not withdraw women from productive work in the same way. Tasks were also segmented by local custom, crop, season and access to land. Census occupational returns cannot simply be used to rank communities by 'female participation' because enumerators often classified married women through the occupation of a male household head or treated subsistence tasks as domestic. The more defensible approach is to combine occupation tables with settlement reports, labour studies and the material requirements of cultivation. Female economic activity was structured by hierarchy, but it was not reducible to a single community rule.

64.5 Seclusion and purdah were social practices with unequal reach

Colonial observers often used purdah as a shorthand explanation for female illiteracy, limited medical access or restricted mobility. That language can obscure the fact that seclusion varied by wealth, locality, religion, status aspiration and life stage. For households able to sustain it, control over women's movement could become a sign of respectability. For labouring households whose survival required women's field, market or service work, comparable seclusion was materially difficult. Elite norms could nevertheless influence wider ideas of honour and marriage even when everyday practice differed. Historians should therefore avoid describing whole districts or communities as uniformly secluded. Purdah mattered both as lived constraint and as an administrative category through which officials explained problems of schooling and medicine, but its operation had to be negotiated in particular households.

64.6 Colonial institutions often entered through the language of respectable domesticity

Girls' education, female medical aid and reformist print frequently justified new institutions by promising to improve the household rather than to dissolve it. A literate girl might be presented as a better mother; female medical personnel as necessary because respectable women could not consult male doctors; domestic science as education suited to women's future roles. This language could make institutional innovation socially acceptable while also limiting the horizon of what counted as appropriate female knowledge. The tension is central to colonial modernity: education and professionalisation opened real capacities, yet they were often framed through revised domestic ideals. Women themselves could use the skills acquired under these terms for purposes that exceeded official or familial expectations—reading, correspondence, teaching, public work and political organisation.

Figure 252 — Institutional domains through which colonial modernity affected women

64.7 Female education expanded from a very narrow base

The educational transformation described in Chapter 60 was strongly gendered. Government schools, mission initiatives, private teaching, zenana instruction and later girls' schools created more points of entry, but access remained much narrower for girls than for boys. Distance to school, the availability of female teachers, fears about mixed schooling, marriage age, household labour needs and the perceived usefulness of formal education all shaped attendance. Expansion therefore cannot be measured only by counting institutions. A district might gain schools while large rural areas remained beyond practical reach. The historical significance of the new system lies in the creation of a durable institutional claim that girls were educable subjects of public policy, even though implementation was slow and socially selective.

64.8 Zenana instruction shows how schooling adapted to seclusion

Where families resisted sending girls to public schools, zenana education and home-based instruction offered an intermediate form. Such arrangements reveal negotiation rather than a simple opposition between 'tradition' and 'modern education'. Instruction could be brought inside socially protected domestic space, often through female teachers or supervised arrangements. The model had obvious limitations: it was harder to standardise, inspect and expand than ordinary schooling, and it often reached households with sufficient resources or institutional contact. Yet its existence demonstrates that demand for literacy could grow before families accepted the spatial routines of a public classroom. In north Bihar and other parts of the province, official discussion of female education repeatedly treated the problem of access as inseparable from household norms governing respectable mobility.

64.9 The 1904–1915 education records show an increasingly specific female policy

Bihar State Archives preserves a revealing sequence of colonial education proceedings. A 1904 file concerned the expansion of female education through model primary and high schools for girls, zenana education, and the use of schoolmasters' wives as mistresses. In 1911, administrative responsibility for model girls' primary schools was shifted toward inspectresses of girls' schools. In 1914 officials discussed special

primary schools for Muhammadan girls, and in 1915 the province framed rules for advisory committees and a curriculum for girls' primary and middle schools. These records do not prove rapid mass enrolment. They show something different: female education had become a distinct administrative problem with specialised personnel, curricula and institutional devices rather than a marginal add-on to boys' schooling.

64.10 Girls' curricula could widen literacy while reproducing gender difference

Separate curricular planning often combined reading, writing and arithmetic with subjects defined as suitable preparation for domestic and maternal roles. This was not unique to Bihar and Orissa; it formed part of a wider colonial and reformist debate about what educated womanhood should mean. The result was double-sided. Girls gained access to literacy and formal schooling, but the educational system could simultaneously naturalise a gendered division of knowledge. The proper historical question is therefore not whether girls' curricula were simply progressive or conservative. It is how institutional schooling created new competencies and credentials while embedding them in a language of social respectability, domestic efficiency and differentiated futures for boys and girls.

64.11 Census literacy figures show growth and a persistent gulf

The censuses of 1921 and 1931 make the gender gap impossible to miss. The all-India 1931 review reported an increase in the absolute number of literate females in Bihar and Orissa between the two censuses, but the province still stood among the regions with a very large disparity between male and female literacy. Absolute totals must be used cautiously because the provincial unit was much larger than Mithila, Vajji and Anga and because definitions of literacy and age group matter. Even so, the broad conclusion is secure: late-colonial institutional growth did not produce anything approaching equal literacy. Urban access, household wealth and community-specific educational infrastructure mattered greatly, while the rural majority remained poorly served.

64.12 The 1919 Primary Education Act changed the language of state responsibility

The Bihar and Orissa Primary Education Act of 1919 provided a statutory framework for extending primary education through local authorities. Its significance for girls lies less in an assumption of immediate compulsory attendance than in the inclusion of both boys and girls within an expanding field of public educational responsibility. Local implementation depended on finance, notification, schools, teachers and parental cooperation. The law therefore widened the administrative horizon without erasing the constraints identified in provincial education reports. It also illustrates a recurring pattern in this chapter: legislation could create a new institutional possibility long before that possibility became an everyday reality for most women or girls.

Figure 253 — Selected legal and institutional milestones affecting women, 1856–1935

64.13 Print created new female readerships without making reading universally public

The print culture examined in Chapter 61 intersected with women's lives through textbooks, religious literature, household manuals, reform tracts, newspapers and correspondence. Reading did not require a woman to become a public author. A literate household member could read aloud; printed texts could circulate through family and neighbourhood networks; women could participate in textual culture through listening, memorisation and dictated letters. Advice literature often addressed women as managers of domestic morality, hygiene and child-rearing, thereby turning the household into a field of reform. Such texts are evidence of prescriptive ideals rather than transparent descriptions of actual behaviour. Their importance lies in the growing assumption that domestic life itself could be reorganised through print.

64.14 Script change affected access but did not erase older literacy worlds

The increasing dominance of Devanagari in printed Maithili and Hindi changed the material conditions of reading for women as it did for men, but manuscript cultures did not vanish at the moment print expanded. Tirhuta/Mithilakshar continued in genealogical, ritual, scribal and symbolic contexts, while Devanagari benefited from growing school and printing infrastructure. The gendered history of this transition is difficult to quantify because women's informal and domestic literacy is poorly documented. It would be unsafe to assume that the script preferred by printed institutions exactly matched every household practice. The most defensible conclusion is that colonial schooling and print progressively privileged scripts that were cheaper and easier to reproduce within modern institutions, thereby reshaping the opportunities through which new readers—women included—encountered written Maithili and related vernaculars.

64.15 Consent law and marriage law addressed different legal questions

The Age of Consent Act of 1891 is frequently misdescribed as a law that raised the legal age of marriage. It did not. It amended criminal law so that sexual intercourse with a girl below twelve was treated as rape regardless of marital status, raising the relevant threshold from ten to twelve. Child marriage could therefore remain legally valid even while consummation below the consent threshold became punishable. This

distinction is essential because colonial debate often conflated marriage, puberty, sexual consent and bodily harm. For the regional history of women, the act is evidence of a new willingness by the colonial state to intervene in an intimate sphere, but it should not be read as proof that early marriage disappeared or that girls acquired general marital autonomy.

64.16 The 1856 widow-remarriage law altered legal capacity more than social practice

The Hindu Widows' Remarriage Act of 1856 removed legal obstacles to the remarriage of Hindu widows who chose it, but legislation did not make widow remarriage socially acceptable in every group. Regional practice varied substantially. Some communities permitted or normalised forms of remarriage; others attached severe stigma to it, especially among status-conscious upper groups. The act itself also linked remarriage to consequences for certain property interests in the deceased husband's estate, reminding us that reform legislation could both enable and condition a new legal choice. A history of colonial modernity should therefore distinguish legal validity from social feasibility. A widow's actual options depended on age, kin support, children, property, caste or community rules and local marriage markets as much as on the text of a statute.

64.17 The Child Marriage Restraint Act created a marriage-age rule but enforcement remained difficult

The Child Marriage Restraint Act of 1929, which came into force in 1930, marked a further shift by directly restraining marriages below prescribed ages—fourteen for girls and eighteen for boys under the original law. Its passage followed decades of debate in which Indian reformers, women's organisations and legislators played central roles. The act did not automatically end child marriage. Registration was incomplete, proof of age could be uncertain, and enforcement depended on complaints and local administrative capacity. Census discussion in the early 1930s itself showed how persistent early marriage remained in Bihar and Orissa. The law is therefore best understood as part of a changing normative and legal field rather than as a clean chronological boundary between 'child marriage' and 'modern marriage'.

64.18 Marriage age, widowhood and education were structurally connected

Schooling, marriage timing and widowhood cannot be analysed as separate social questions. Early marriage could shorten a girl's period of attendance or prevent entry into school altogether; widowhood at a young age could radically alter residence, labour and dependence; and the perceived need to protect marriageability could shape parental decisions about mobility and co-education. Conversely, the expansion of girls' schools and new educated occupations created constituencies for later marriage and continued study, at least among families able to make use of them. The interaction was recursive rather than linear. Education could influence marriage expectations, while marriage practices determined who remained in education long enough to benefit from it.

64.19 Colonial courts made family relations legible through legal categories

Property, maintenance, guardianship, marriage validity and inheritance entered colonial courts through codified statutes, case law and interpretations of personal law. Litigation created a rich archive, but it must be handled carefully. Court disputes disproportionately represent households with something worth contesting and people able to pursue legal remedies. Judicial categories can also make flexible social practices appear more fixed than they were outside litigation. For women, however, the courts could become real arenas in

which claims over maintenance, property or marital status were asserted. Colonial modernity thus expanded the documentary and procedural forms through which family conflict could be articulated, even while access to those procedures remained unequal.

64.20 Female medical aid responded partly to the politics of access

Colonial medical institutions repeatedly confronted the fact that many women—especially in households observing seclusion—were reluctant or unable to consult male doctors. The late nineteenth-century movement for female medical aid, associated nationally with the Dufferin Fund established in 1885, sought women doctors, hospitals, nurses and training facilities. This was at once a health intervention and a social accommodation: the institution adapted to gendered restrictions on contact in order to extend biomedical care. The resulting system was unevenly distributed and far more accessible in towns than in much of the countryside. Nevertheless, it created new professional roles for women and a new administrative category of 'female medical aid' that provincial governments increasingly reported and funded.

64.21 Lady doctors and women's hospitals did not solve rural access

By the late colonial period, Bihar government reports could point to lady doctors attached to major institutions, grants from the provincial Dufferin Fund committee, and maternity or child-welfare centres. Such evidence demonstrates institutional growth, not universal coverage. The distance between a village and a hospital, transport cost, seclusion, trust, the availability of female staff and the urgency of illness all influenced actual use. Rural women continued to depend heavily on household remedies, local practitioners and dais. The social history of medicine is therefore not a story in which scientific institutions simply replaced 'traditional' care. It is a history of plural options structured by geography, money, gender norms and the expanding regulatory power of the state.

64.22 Dais became objects of training, classification and regulation

Childbirth made the experienced dai one of the most important female health practitioners in everyday life, yet official medicine often described dais through a deficit model—untrained, unhygienic or in need of supervision. Training schemes and maternity programmes attempted to change practice without being able to dispense with the local birth attendant. The Bihar and Orissa Nurses Registration Act of 1935 formalised this regulatory trajectory by creating categories for nurses, health visitors, midwives, trained dais and dais, and by establishing registration and training mechanisms. The statute is significant because it shows the state translating an existing female occupation into a graded professional hierarchy. That process could improve training and accountability, but it also relocated authority from community recognition toward certificates, councils and official standards.

Figure 254 — Layered medicalisation of female health and childbirth

64.23 Maternal and child welfare made reproduction a field of public policy

Late-colonial maternity and child-welfare initiatives widened the medical gaze from treatment of acute illness to pregnancy, childbirth, infant care, nutrition and hygiene. Health visitors, midwifery centres and child-welfare centres embodied a new claim that maternal practices were matters of public administration. Such programmes could provide valuable care, but their language also placed women's bodies at the intersection of demographic concern, medical expertise and domestic reform. The effect was not merely medical. Ideas about cleanliness, breastfeeding, infant care and household management circulated through clinics, pamphlets and instruction, linking the welfare state in embryo to the reform of everyday domestic behaviour.

64.24 Migration redistributed women's labour inside and beyond the household

Chapter 63 showed that male-dominated circular migration could leave women with greater responsibility for cultivation, consumption management, debt relations, children and elderly dependants. This did not automatically translate into greater authority over land or cash, because remittances, property rights and senior kin could constrain decision-making. At the same time, women also migrated—as wives, domestic workers, agricultural labourers, plantation workers and members of recruited families. Colonial census categories complicate the picture because marriage migration and labour migration are often difficult to separate. The gendered history of mobility must therefore include both women who moved and women whose workload and responsibilities changed because others moved.

64.25 Wage labour did not exhaust women's economic activity

Factories, plantations, railway-connected markets and urban service work created visible forms of female wage labour, but most women in the region remained connected to agrarian and household economies. Paid employment should therefore not be treated as the sole marker of 'economic participation' or modernity. A woman producing food, managing livestock, processing crops, making household goods, assisting a family trade or maintaining a migrant household might contribute substantially to income and subsistence without appearing as an independent worker in official statistics. The conceptual error of equating wages with work

reproduces the bias of the colonial archive. A fuller economic history measures the organisation of labour, not only the existence of a pay packet.

64.26 Scarcity and famine had gendered household consequences

The famine and scarcity regimes discussed in Chapter 58 were experienced through household allocation. When grain prices rose or employment failed, women often managed the immediate arithmetic of food, fuel and care. Distress could force the sale of ornaments or household assets, increase dependence on credit, alter marriage arrangements, encourage migration or push women into more precarious forms of labour. Relief records rarely capture these intra-household negotiations in detail. Yet the gendered consequences of crisis are essential to understanding colonial welfare: a ration, wage or relief work test was received by a household whose members did not necessarily bear deprivation equally. The history of women under colonialism therefore belongs inside economic history, not in a separate social appendix.

64.27 Nationalism converted selected domestic practices into public politics

The Gandhian movements after 1919 created new routes through which women could participate without first entering conventional party office. Spinning, khadi, boycott, fundraising, picketing and processions linked household practices to anti-colonial mobilisation. This repertoire was powerful precisely because it revalued activities already associated with women while allowing them to acquire public meaning. Yet participation remained uneven. Families differed in their willingness to permit public activism, and women with education, organisational connections or politically engaged kin often had advantages. Nationalism could widen the legitimate sphere of female action while still praising sacrifice, domestic virtue and moral authority in distinctly gendered terms.

64.28 By 1942 women and girl students were visible political actors in the region

The Quit India upsurge makes the change in public visibility especially clear. Bihar political records and later histories describe women and girl students joining processions, picketing institutions, carrying flags and courting arrest. In Darbhanga, student processions included women; in Monghyr, girl students took part in demonstrations and flag-hoisting actions; elsewhere in the province women organised marches and public meetings. These episodes should not be used to imply that all women had entered politics. Their importance lies in the legitimacy of female public action having expanded far beyond the narrow social reform circles of the nineteenth century. Political participation became another arena in which colonial authority, family respectability and women's own claims to citizenship were negotiated.

Figure 255 — Gendered visibility in the colonial archive

64.29 Nepal Mithila provides a necessary limit to the colonial category

The northern cultural region crossed a frontier into Nepal, which was not governed as a British colony. Educational, legal and medical changes in British India could nevertheless influence border markets, elite networks, print circulation, pilgrimage and migration. It would therefore be misleading either to treat Nepal Mithila as outside the story or to label its institutions 'colonial' in the same sense as Darbhanga, Muzaffarpur, Monghyr or Bhagalpur. The comparison is analytically useful because it separates direct colonial administration from wider regional modernity. Chapter 70 examines language, education and cultural institutions in Nepal on their own political terms; here the point is simply that the India–Nepal interaction zone transmitted ideas and people across unequal state regimes.

64.30 Conclusion: colonial modernity expanded options while reorganising constraints

For women in Mithila, Vajji and Anga, colonial modernity created new institutions, legal categories and public roles without producing a single trajectory of liberation. Girls' schooling expanded but remained deeply unequal; law altered the formal treatment of widow remarriage, consent and child marriage while social enforcement stayed uneven; medical institutions created new female professions but rural care remained plural; labour migration redistributed household work; print reformulated domestic ideals; and nationalism opened visible forms of public action. The central transformation was therefore not the disappearance of household, caste, community or patriarchy. It was the multiplication of arenas in which these structures could be negotiated—school, court, clinic, newspaper, labour market and political street. Women's history becomes clearest when those arenas are studied together and when the silences of the colonial archive are treated as evidence about power rather than as evidence of inactivity.

Table 64.1 — Evidence for women and colonial modernity: strengths and limits

Source / evidence	What it can establish	Main interpretive caution
Census reports	Literacy, marital status, age structure, selected occupations, migration and sex ratios	Administrative definitions may undercount unpaid work and cannot reveal household bargaining or

Source / evidence	What it can establish	Main interpretive caution
		motives
Education proceedings and school reports	Girls' schools, enrolment, curricula, inspectresses, teacher policy and institutional expansion	School presence does not equal attendance; official categories privilege formal instruction
Statutes, court cases and legal reports	Formal rules on widow remarriage, consent, marriage age, maintenance, guardianship and professional registration	Legal possibility or prohibition does not measure social acceptance, enforcement or accessibility
Medical and public-health reports	Hospitals, lady doctors, maternity centres, nurses, midwives, trained dais and patient institutions	Urban and institutional care is over-represented; household and local therapeutic practice is harder to see
District gazetteers and settlement records	Local labour, seclusion, schooling, markets, migration, agrarian conditions and public institutions	Official observation can generalise elite norms and freeze fluid social practice into district descriptions
Labour and migration enquiries	Women's wage work, plantation recruitment, family migration, coercion and labour regulation	Problem-focused enquiries over-represent regulated or controversial labour circuits
Newspapers, reform tracts and advice literature	Debates over education, domesticity, marriage, hygiene, nationalism and respectable womanhood	Prescriptive texts reveal ideals and controversies more directly than everyday compliance
Political files, memoirs, letters, songs and oral histories	Protest, public participation, household experience, memory, aspiration and under-recorded work	Survival, dating, authorship and representativeness require close source criticism

PART VIII

NEPAL MITHILA / MADHESH AS A SOCIAL AND ECONOMIC REGION

Chapters 65–73

Chapter 65 — The Historical India–Nepal Borderland Economy

The India–Nepal boundary across Mithila and the wider eastern Tarai/Madhesh did not create two self-contained economies. It cut across an older lowland–foothill–valley system in which cultivators, pastoralists, merchants, pilgrims, craftsmen, revenue farmers, carriers and state agents moved through linked markets and seasonal routes. From the late eighteenth century onward, Gorkha consolidation, Company expansion, the Anglo–Gorkha War, boundary demarcation, customs administration and railway construction altered the terms of movement without abolishing the economic continuities of the plains. This chapter therefore treats the border as an institution embedded in a corridor: politically real, fiscally consequential and increasingly surveyed, yet continually crossed by commodities, labour, credit, kinship and pilgrimage.

65.1 A borderland economy existed before a fixed international line

The historical economy joining north Bihar to the Nepal Tarai and the Himalayan interior was older than the modern boundary. River systems, alluvial plains, forest belts and foothill passes produced a north–south gradient of exchange. Grain, livestock, cloth and manufactured goods moved toward the hills; forest products and highland commodities moved toward low-country markets. Political jurisdictions changed repeatedly, but the commercial logic of short-haul movement from village to hat, hat to customs point, and customs point to a long-distance route remained durable. The term borderland is therefore more accurate than frontier only if it does not imply political vagueness. States claimed revenue and sovereignty here, yet their lines intersected economic fields whose scale was set by ecology, transport cost and social networks as much as by jurisdiction.

65.2 Mithila, Tarai and Madhesh are overlapping historical frames, not synonyms

The lowlands north of the present Bihar boundary have been described by different names in different periods. Tarai often referred to the low, forested or malarial belt south of the hills; Madhesh could denote plains country more broadly; Mithila referred to a historical-cultural region whose linguistic and ritual connections crossed the later international boundary. Modern Madhesh Province is a contemporary federal unit and must not be projected backward as though it were the administrative container of eighteenth- or nineteenth-century evidence. In this chapter, place names such as Mahottari, Saptari, Rautahat, Bara and Parsa are used when sources permit, while Mithila/Madhesh is retained as the larger social-economic frame. This prevents both nationalist partition of a connected history and an opposite error in which political borders are treated as unreal.

65.3 The corridor linked the Ganga plain, Tarai markets, foothill gates and Kathmandu

By the late eighteenth and early nineteenth centuries, travelers described routes that joined the Company's low-country territory to the Tarai, Hetauda and Bhimphedi before the difficult ascent toward the Kathmandu Valley. Buchanan-Hamilton identified Patna as the principal low-country mart for the commerce he observed, while Kirkpatrick's earlier mission recorded the practical geography of passes, rivers and staging places. These accounts are selective and often written from diplomatic or military viewpoints, but their route descriptions reveal an economy made of linked zones rather than a single road. A merchant

could depend on river ferries, pack animals, forest halts, customs posts and hill porters within one journey. The corridor's economic geography therefore changed gradually as one transport layer was added to another.

Figure 256 — The India-Nepal borderland economy as connected zones

Schematic, not to scale. The political boundary mattered, but it cut across older ecological and commercial corridors.

Figure 256 — The India-Nepal borderland economy as connected zones

65.4 Patna's importance came from aggregation, finance and connection to wider markets

Patna's role in the Nepal trade was not simply that of the nearest large city. It was a major Gangetic commercial centre able to aggregate imported and local goods, connect merchants to eastern Indian and overseas commodity chains, and provide money, credit and specialized wares. Buchanan-Hamilton's account describes goods moving from the low country to Nepal and onward toward Tibet, while highland products descended toward Patna. The city therefore functioned as an entrepôt within a much larger network. For Mithila and the eastern Tarai this matters because intermediate towns did not need to rival Patna in size to participate in the same system. Muzaffarpur, Darbhanga, border hats and later railheads acted as collection, redistribution and transfer points between local production and long-distance commerce.

65.5 Commodity flows were reciprocal but not symmetrical

The route carried different bundles in different directions. Buchanan-Hamilton lists low-country supplies such as buffaloes, goats, cotton cloth, European manufactures, metal wares, spices, betel products, tobacco and other consumer goods moving northward, while musk, borax, mineral and animal products, highland textiles or fibers and other commodities moved south. The exact mix varied by period, route and political condition. Reciprocity therefore did not imply an equal balance of trade or equal bargaining power. It meant that the border economy was sustained by complementary ecological zones. Plains agriculture, urban demand, hill transport and trans-Himalayan exchange were connected through successive markets, each taking a margin and each exposed to seasonal interruption.

65.6 Parsa-Makwanpur was a strategic commercial gate as well as a military route

The route through Parsa toward Hetauda and Makwanpur illustrates how commerce and strategy overlapped. Buchanan-Hamilton described segments that could carry laden cattle and, with improvement,

carts; he also noted forest conditions, unhealthy seasons and duties collected at staging points. Hetauda offered accommodation to merchants before the harder ascent through Bhimpheedi. The same terrain interested military observers because whoever controlled the passes controlled access toward Kathmandu. This dual character helps explain why road improvement could be politically sensitive. A road that lowered transport costs for trade also altered the strategic permeability of the state. Economic infrastructure in the borderland was therefore never purely economic.

65.7 Eastern Tarai districts formed a fiscal-commercial belt within Gorkha administration

For the eastern plains, Buchanan-Hamilton described Saptari and Mahottari alongside the wider set of lowland jurisdictions connected with Rautahat, Bara and Parsa. His evidence shows forts, market places, land-rent collection, sayar or market duties, and golas or customs houses. These were not accidental appendages to a hill kingdom. The Tarai generated grain, pasture, timber and customs income while also providing routes linking the low country to the hills. At the same time, the administrative map was unstable: jurisdictions could be rearranged, revenue farms reassigned and customs points moved. The economic region should therefore be reconstructed from functions—collection, storage, market exchange and transit—rather than assuming that every named district had fixed borders identical to later maps.

65.8 Janakpur was already a pilgrimage place embedded in a market landscape

Buchanan-Hamilton described Janakpur as a place of pilgrimage within the Saptari–Mahottari administrative zone and recorded ten market places in that broader district. The combination matters. Pilgrimage generated episodic concentrations of consumers, animals, food sellers, ritual suppliers and transport workers; nearby market and customs institutions connected those gatherings to everyday trade. Janakpur's later urban growth belongs to Chapter 66, but its earlier economic function cannot be reduced to religion alone. Sacred mobility was one of the recurring mechanisms through which commodities and information crossed the political boundary. Pilgrims did not travel outside the economy: they hired carriers, bought food, exchanged coin, purchased ritual goods and created seasonal demand.

65.9 Golas and hats were institutions that made movement taxable

The gola in early nineteenth-century accounts was at once a customs point, mart and administrative node. Buchanan-Hamilton observed that such customs houses could shift location and were increasingly placed near frontiers. This mobility is important: it shows a state trying to intercept flows whose routes were older and more flexible than the administrative grid. Hats performed a complementary role at shorter range, bringing cultivators, traders and consumers into periodic exchange. Together, hats and golas converted movement into assessable revenue. They also created opportunities for evasion, bargaining and monopoly. A boundary mattered economically when officials could force trade through a taxable point; where geography allowed many paths, enforcement remained incomplete.

65.10 Early nineteenth-century revenue data show customs were a major fiscal interest

Buchanan-Hamilton's c.1809 snapshot for Saptari and Mahottari reports land rent of 68,957 rupees, customs at golas of 29,833 rupees, market duties of 12,985 rupees, and additional receipts from pasture, timber cutting, timber boats and other dues. The figures must be treated as administrative claims from one documentary moment rather than a complete national account. Even so, they demonstrate that customs and

market taxation were not marginal beside agriculture. Trade, forest extraction and transport were embedded in the fiscal structure. The same source notes that frontier disputes interrupted commerce and threatened the profits of a customs farmer, directly linking territorial uncertainty to revenue risk.

Figure 257 — Reported fiscal receipts in Saptari-Mahottari, c.1809

65.11 Revenue farming joined state authority to private risk-taking

Customs and market dues were often farmed. A contractor paid or promised the state a fixed amount and then attempted to recover more from actual collections. This arrangement gave the state predictable revenue while shifting collection risk to intermediaries, but it could encourage aggressive extraction or attempts to monopolize trade. Buchanan-Hamilton's description of a customs farmer affected by frontier disruption captures the political economy of the system: profit depended on keeping goods within taxable channels. Merchants, meanwhile, had incentives to negotiate, reroute or conceal consignments. The border economy thus involved a three-cornered relationship among state, revenue intermediary and mobile trader rather than a simple state-versus-smuggler opposition.

65.12 Forest, timber and pasture linked ecology directly to fiscal revenue

The Tarai's forests were not merely obstacles between plains and hills. They supplied timber, grazing, catechu, wildlife products and land that could eventually be reclaimed for cultivation. Hamilton's revenue categories include charges on timber cutters, boats carrying timber and buffalo pasture. The economic value of the forest therefore came from both extraction and controlled access. Yet forest density and malaria also raised transport and settlement costs. States could have reasons to preserve forest as a defensive belt, exploit it for revenue, or clear it for cultivation, and these objectives could conflict. Later railway and road construction would intensify extraction, but the fiscal significance of forest resources was already visible before mechanized transport.

65.13 The Sugauli settlement transformed the territorial grammar of the economy

The Anglo-Gorkha War of 1814–16 emerged partly from disputes over land, tribute and jurisdiction on a frontier where older political claims overlapped. The Sugauli Treaty attempted to replace that ambiguity with a more legible territorial settlement. For the eastern and central lowlands, this meant that economic

activities previously embedded in overlapping claims were increasingly divided by a surveyed international boundary. The line did not stop cultivation or trade, but it changed who could tax them and where disputes were adjudicated. Bernardo Michael's work is especially useful here: the making of a linear border was not simply the discovery of a natural divide; it was a state-making project imposed on older, discontinuous territorial practices.

65.14 The 1816 restoration shows that the first treaty map did not settle the border once for all

The territorial settlement was modified within months. A supplementary arrangement restored much of the central and eastern Tarai between the Kosi and Rapti to Nepal, subject to boundary settlement and exceptions. This rapid revision warns against treating 1816 as a single instantaneous border event. Commissioners still had to identify lines on the ground, reconcile villages and property claims, and manage the mismatch between maps and lived agrarian space. For traders and cultivators, the practical question was not only which sovereign claimed a tract, but which collector appeared, which customs point operated and whether older access rights continued. Border-making was therefore a process with economic consequences, not a date alone.

65.15 The 1860 restoration belongs to the wider history of the border, though west of Mithila

After Nepal aided the British during the uprising of 1857, additional Tarai territory in the west was restored in 1860, later known as Naya Muluk. This lay outside the core Mithila–Madhesh focus of this chapter, yet it matters comparatively because it confirms that the Nepal–India boundary remained the product of treaty revision and political bargaining. It also contributed to later understandings of a long, traversable frontier between the two states. The eastern borderland should not be explained from western events, but the all-Nepal chronology helps distinguish local continuities from changes in the interstate framework.

Figure 258 — From negotiated frontier to transport-linked international boundary

Dates mark institutional turning points; everyday movement, cultivation and exchange did not reset suddenly at treaty dates.

Figure 258 — From negotiated frontier to transport-linked international boundary

65.16 Boundary surveys made territory more legible while leaving social geographies connected

Nineteenth-century demarcation introduced pillars, surveyed lines and a bureaucratic archive of boundary disputes. This strengthened the state's ability to distinguish jurisdictions, but it did not make the social geography on each side distinct. Villages remained tied by marriage, shared markets, religious institutions, grazing and labor movement. The historical lesson is not that the border was fictitious; it is that territorial legibility and social integration increased at the same time. A better surveyed line could coexist with dense crossing because the economy depended on controlled passage rather than absolute closure.

65.17 Rana rule sought revenue and security through the Tarai market system

Under Rana rule, the Tarai remained a major source of land, forest and customs revenue. The Government of Nepal's History of Nepal Customs emphasizes the long practice of establishing markets and trade points in the plains in order to channel commerce and strengthen state control. Revenue collection, security and commercial policy were intertwined. The state could encourage particular marts, restrict routes, farm duties or reserve resources. This did not create a perfectly centralized customs regime: local officials and contractors remained crucial, and the long border made enforcement uneven. Still, the persistence of customs institutions shows that the Tarai was central to the fiscal relationship between Nepal and British India.

65.18 Settlement and cultivation expanded through cross-border labor and tenancy networks

Agricultural expansion in the Tarai depended heavily on people able to clear land, manage wet cultivation and survive or seasonally avoid disease environments. Migration from adjoining districts of northern India became one component of this process, alongside long-established Tarai communities and movements from the hills. The resulting agrarian world was transborder in social composition even when land revenue was collected by the Nepal state. Chapter 67 examines tenure in detail; here the economic point is that labor supply and cultivation knowledge crossed the boundary more readily than sovereign rights to land. The border could define the treasury receiving rent without defining the origin of every cultivator or trader.

65.19 Malaria and seasonality were transport institutions as much as health conditions

The forested Tarai acquired a reputation for dangerous warm-season disease. Early travelers repeatedly tied route choice and timing to the unhealthy season, and some administrative or commercial movements concentrated in cooler months. Disease therefore structured transaction costs. It influenced when merchants travelled, where they halted, which populations could remain year-round and how rapidly roads or settlements expanded. The historical border economy was seasonal not simply because rivers rose and crops ripened, but because health risks changed the effective accessibility of the lowlands. Later malaria control would transform settlement patterns dramatically, but before that transformation disease itself acted as a gatekeeper.

65.20 Grain and livestock trade tied household subsistence to cross-border prices

Rice and other grains were among the most consequential commodities because they connected peasant production to urban, military and hill demand. Loaded cattle moving toward the foothills carried grain; livestock themselves were traded; shortages on one side could draw supplies from the other when routes and
